OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

1903-1904

GENERAL OFFICERS

PRESIDENT—FRANK BILLINGS	100 State St., Chicago
PRESIDENT-ELECT—JOHN H. MUSSER	1927 Chestnut St., Philadelphia
FIRST VICE-PRESIDENT—G. C. SAVAGE	Nashville, Tenn.
SECOND VICE-PRESIDENT—ISADORE DYER	New Orleans
THIRD VICE-PRESIDENT—C. LESTER HALL	Kansas City, Mo.
FOURTH VICE-PRESIDENT—GEORGE F. JENKINS	Keokuk, Iowa
SECRETARY-EDITOR—GEORGE H. SIMMONS	103 Dearborn Ave., Chicago.
TREASURER—HENRY P. NEWMAN	Chicago
CHAIRMAN COMMITTEE OF ARRANGEMENTS—B. C. PENNINGTON	Atlantic City, N. J.

BOARD OF TRUSTEES.

W. W. Grant, Denver, 1904.
John F. Fulton, St. Paul, Minn., 1904.
T. J. Happel, Chairman, Trenton, Tenn., 1904.
E. E. Montgomery, Secretary, Philadelphia, 1905.
H. L. E. Johnson, Washington, D. C., 1905
A. L. Wright, Carroll, Iowa, 1905.
William H. Welch, Baltimore, 1906.
Miles F. Porter, Ft. Wayne, Ind., 1906.
M. L. Harris, Chicago, 1906.

JUDICIAL COUNCIL.

Term expires 1904: T. C. Martin, Ohio; J. B. Roberts, Pennsylvania; Christopher Tompkins, Virginia.

Term expires 1905: Philip Marvel (Chairman), New Jersey; George Cook, New Hampshire; N. S. Davis, Jr., Illinois.

Term expires 1906: F. H. Wiggin (Secretary), New York; G. B. Gillespie, Tennessee; D. C. Peyton, Indiana.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, Alexander Lambert, 125 East Thirty-sixth St., New York; Secretary, J. L. Miller, 100 State St., Chicago. Executive Committee—J. M. Anders, Philadelphia; Frank A. Jones, Memphis, Tenn.; W. S. Thayer, Baltimore.

OBSTETRICS AND DISEASES OF WOMEN—Chairman, L. H. Dunning, 224 North Meridian St., Indianapolis; Secretary, C. L. Bonifield, 432 West Fourth St., Cincinnati, Ohio. Executive Committee—Henry P. Newman, Chicago; J. H. Carstens, Detroit, Mich.; A. Palmer Dudley, New York City.

SURGERY AND ANATOMY—Chairman, Charles A. Powers, Fourteenth and Stout Sts., Denver, Colo.; Secretary, E. Wyllys Andrews, 100 State St., Chicago. Executive Committee—A. J. Ochsner, Chicago; DeForest Willard, Philadelphia; James E. Moore, Minneapolis.

HYGIENE AND SANITARY SCIENCE—Chairman, G. T. Swarts, 70 Waterman St., Providence, R. I.; Secretary, J. S. Fulton, 1809 St. Paul St., Baltimore, Md. Executive Committee—Arthur R. Reynolds, Chicago; H. M. Bracken, Minneapolis, Minn.

OPHTHALMOLOGY—Chairman, R. L. Randolph, 816 Park Ave., Baltimore; Secretary, A. E. Bulson, Jr., Ft. Wayne, Ind. Executive Committee—J. A. Lippincott, Pittsburg; Frank Allport, Chicago; John E. Weeks, New York City.

DISEASES OF CHILDREN—Chairman, Charles G. Kerley, 113 West Eighty-third St., New York; Secretary, C. F. Wahrer, Ft. Madison, Iowa. Executive Committee—Samuel W. Kelley, Cleveland; H. M. McClanahan, Omaha; John C. Cook, Chicago.

STOMATOLOGY—Chairman, G. F. Eames, 31 Beacon St., Boston; Secretary, Eugene S. Talbot, 103 State St., Chicago. Executive Committee—R. R. Andrews, Cambridge, Mass.; A. H. Peck, Chicago; M. L. Rhein, New York.

NERVOUS AND MENTAL DISEASES—Chairman, F. Savary Pearce, 1409 Locust St., Philadelphia; Secretary, David I. Wolfstein, 22 West Seventh St., Cincinnati. Executive Committee—H. A. Tomlinson, St. Peter, Minn.; Richard Dewey, Wauwatosa, Wis.; F. W. Langdon, Cincinnati.

CUTANEOUS MEDICINE AND SURGERY—Chairman, Henry G. Anthony, 465 Dearborn Ave., Chicago; Secretary, R. R. Campbell, 204 Dearborn St., Chicago. Executive Committee—W. L. Baum, Chicago; Henry W. Stelwagon, Philadelphia; John A. Fordyce, New York.

LARYNGOLOGY AND OTOLOGY—Chairman, J. F. Barnhill, Newton Claypool Bldg., Indianapolis; Secretary, Otto T. Freer, 288 Huron St., Chicago. Executive Committee—J. N. Mackenzie, Baltimore; G. Hudson Makuen, Philadelphia; Geo. L. Richards, Fall River, Mass.

MATERIA MEDICA, PHARMACY AND THERAPEUTICS—Chairman, O. T. Osborne, 252 York St., New Haven, Conn.; Secretary, C. S. N. Hallberg, 358 Dearborn St., Chicago. Executive Committee—N. S. Davis, Jr., Chicago; George F. Butler, Alma, Mich.; Solomon Solis-Cohen, Philadelphia.

PATHOLOGY AND PHYSIOLOGY—Chairman, Joseph McFarland, Medico-Chirurgical College, Philadelphia; Secretary, Henry A. Christian, Boston City Hospital, Boston. Executive Committee—L. Hektoen, Chicago; Frank B. Wynn, Indianapolis; Victor C. Vaughan, Ann Arbor, Mich.

Address.

OBSERVATIONS ON THE TEACHING OF CLINICAL MEDICINE.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON PRACTICE OF MEDICINE AT THE FIFTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT NEW ORLEANS, MAY 5-8, 1903.

WILLIAM SYDNEY THAYER, M.D.
BALTIMORE.

A hundred years ago the young American republic bought from the French government that great tract of land of which the little frontier city of Nouvelle Orleans was the chief settlement. It is a happy chance that brings us together on the centennial anniversary of the Louisiana Purchase in this metropolis of the south.

One hundred years—a small space of time in the world's history, and yet what events have been crowded into this little period! A hundred years ago the country west of the Mississippi was a wilderness. To-day we meet, a national body, the majority, perhaps, of our members coming from what was then forest and prairie, inhabited only by savage and wild beast. And the young democracy, then all but unknown to the powerful empires of the east, has become the dominating factor in the markets of the civilized world.

In this amazing growth and expansion, in this tremendous accumulation of wealth and strength and power, it was scarcely to be expected that our contributions to science would keep pace with those of the Old World, where accumulated wealth, settled conditions and well equipped institutions of learning naturally tempt the studious and contemplative mind to problems of science and research. And yet, how many of the great discoveries and inventions of the century have come from this new country! In our own branch of learning the record is one of which we may well be proud. The discovery of anæsthesia, the demonstration by Holmes of the contagiousness of puerperal infection, the studies by the students of Louis on typhoid fever, the accomplishments of Bigelow and Sims and McDowell and, lastly, the noble work of Reed, Lazear, Carroll and Agramonte in Cuba and of those who have demonstrated to the world the practical value of their great discoveries—these are but a few examples of an honorable record.

And during this period what a change has come over the condition of medical education in this country! One hundred years ago there were three schools of medicine in America: the Department of Medicine of the College of Philadelphia, the first school of medicine in the United States; the Medical School of Harvard College, and the Dartmouth Medical School of Hanover, N. H. To-day there are over one hundred and fifty.

One hundred years ago only the most favored and fortunate were able to receive anything like a systematic medical training. Not that there were not educated physicians in America. There were in Carolina and New England, in New York and Virginia and Pennsylvania men who had profited by the inspiration and opportunities offered in the best schools of Europe. Many a young man, however, was obliged to begin his studies by "reading medicine" in the office of some older practitioner. His theoretical knowledge was gained from a few books, his main instruction came through the practical observation of disease, gained by assisting at the operations and visits of his preceptor.

In some of our early medical schools the requirements were, however, such as may well surprise those of us who consider the fact that within fifteen years medical schools in this country were giving a degree of doctor of medicine for one year's study. "Although," says Thatcher in 1828 (American Med. Biography, 80, Boston, 1828) "there is no uniform standard of attainment established in order for graduation, in most of our schools it is required that before a student can be admitted to an examination for a degree he must have attained to the age of 21, have studied three years with some regular physician, attended two full courses of lectures on the different branches of medicine, and, if he has not enjoyed the advantages of a college education, he must furnish satisfactory evidence of having made respectable classical attainments, and particularly that he has acquired a competent knowledge of the Latin and Greek languages, has studied mathematics, natural and experimental philosophy, geography and belles lettres. In several of our schools it is required that he shall have attended the clinical practice of some infirmary for a specified term. It is also required that before he can receive his degree he must pass a close examination in the different branches of medicine and write and defend a thesis on some medical subject."

The first schools of medicine were, for the most part, founded in connection with hospitals, and the actual study and observation of the patient was an important part of the student's curriculum. The multiplication of medical schools, however, proceeded with great rapidity. The number of students in some of these institutions was so great as to preclude the possibility that each individual should have sufficient practical experience from the amount of clinical material at hand, while in other instances schools giving the degree of doctor of medicine were established entirely independently of hospitals or infirmaries. Ten years ago the requirements for admission to many of these schools were almost *nil*. It was not uncommon to hear that this or that good

fellow whom one might have known but a day before as the driver of a horse car, had taken his degree in medicine. On investigation it might be found that for the past one or two years he had been attending evening classes, and at the end of this period had stepped from the platform of his car to the bedside of the patient with a degree attesting that he was a competent practitioner of medicine.

Within thirteen years I remember to have heard a colleague relate with pride that he had just accomplished in one year his whole course in medicine at a university with an old and honorable name, practically without clinical advantages. This is, to say no more, far from the ideals of our ancestors.

In the last few years, however, great changes have come into our methods of teaching. Four years' actual work in a medical institution are everywhere required. In our better schools anatomy, physiology, pathological anatomy, pharmacology are no longer taught as they used to be, by lectures to an untrained body of men. In many instances the student begins his medical studies with a training which has already taught him to think and investigate for himself; and our duty as teachers is coming to be rather that of guides and leaders than of simple lecturers.

The teacher to-day must be a student and investigator in his own line. The time is passing when the professor of anatomy or physiology can be a practitioner of medicine. His whole time must now be given to his studies and his teaching, and his immediate duties are not so much to lay facts before his students as to show the student how to find them out for himself.

And so it is in all these branches. The student in the laboratory sees, acts, controls, verifies. While of old he was expected and required to believe what was said to him, he is to-day taught rather to doubt that for which he can not obtain proof. And in like manner throughout the greater part of the course the didactic lecture is passing—such matters the student can read—and is being replaced by practical anatomical, physiological, pathological, pharmacological, experiment and experience. The same methods have come into the teaching of physical diagnosis in its restricted sense, as well as of minor surgery—lectures and demonstrations have largely given way to practical experience in small sections. In some of our schools the teaching in these branches compares with the best that can be found in the world.

But when we arrive at the last stage, the study of pathological physiology in the individual, the observation and care and treatment of the patient, we find, strangely enough, that the advances which have been made in our methods of instruction have not kept pace with those in the other branches. If there be one opportunity in the course of the study of medicine which it would seem most necessary for us to provide for our students, it should be the privilege of watching and studying at the bedside those diseases which they are most likely to meet with in practice. It was the first necessity recognized by our ancestors; it is the first necessity that would be appreciated by any non-medical man; and yet I believe that any one who investigates the matter will realize that it is one of the weakest points to-day in our American system of medical education.

What actual clinical experience does the average medical school of this country offer?

The clinical instruction offered in most of the better schools in this country consists in:

1. Exercises in physical diagnosis proper, which may include good practical work in small sections, but which commonly consist more of lectures and demonstrations than practice and experience.

2. Clinical lectures in which but few, if any, of the class approach the patient.

3. Ward visits which are too often infrequent.

4. Exercises in which students report individually on cases which have been assigned to them for study.

The requirement of a continuous service of students as assistants in hospital wards is almost unknown in this country.

The student who has graduated from such a school may, and often does, leave the institution with a fairly good training in methods of purely physical diagnosis. But how few of us in this room at the time we left the medical school, had ever followed a case of typhoid fever, pneumonia, measles or scarlet fever from beginning to end. And yet there is but one way by which one can learn to recognize and treat these diseases—and that is by bedside experience. Clinics, occasional visits, books and lectures, these weigh but little in the balance. If, as would seem to be the case, the medical records of our late war with Spain reveal a strange lack of familiarity on the part of many physicians with such important diseases as malarial and typhoid fevers, this is due largely to the failure of our medical schools to offer them the necessary bedside experience in the course of their early training.

And again, how few of us as students ever had brought practically before us the vital questions of when and how to administer stimulants in acute infectious diseases; whether, in any given emergency, those drugs should be given which raise or depress the blood pressure. But these are matters which may mean the life or death of the patient, and it is a sad fact that nothing is more common than the administration of nitroglycerin in conditions of profound vasomotor collapse by conscientious men who have missed in their education just that which early and well-directed clinical observation and experience might have brought them. This defect in our medical teaching is further emphasized when we compare the curriculum in most of our schools with that which is required in England and France. In London and Edinburgh, for instance, schools require of a student at least six months' service as a clinical clerk in the medical wards and a similar length of time as a dresser in the surgical department of the hospital. In Paris the student is required to give his whole morning to ward work of this nature for two years—one year in medicine, one in surgery.

That it is desirable that we in America should offer in our schools and require for our license to practice an amount of practical experience equal to that required in Europe is obvious.

Of the necessity for such requirements if we wish to keep pace with the progress of the world and properly educate our medical men there can be no question.

Of their practicability there can also be no doubt when we consider that such methods have been in force for many years in a country where individual liberties are as jealously guarded as they are in England.

Why is it, then, that so serious a defect exists?

The reasons are various and not altogether simple. The more important would seem to be:

1. The absence of state or national laws requiring such work.

2. The multiplicity of medical schools and the existence of many such institutions unconnected with hos-

pitals of sufficient size to furnish material for the instruction of the students.

3. A wide-spread prejudice existing in many hospitals against the admission of students to the wards and against the use of patients in general for purposes of instruction.

1. The first of these reasons is, of course, the most important. Until the states require such experience for a license to practice there will always be schools which will give a degree for less work. It is for us individually as physicians and collectively as we are associated in teaching bodies to strive to raise the standard and to hasten the day when such requirements are put in force.

2. It is the absence of these requirements which is, in great part, responsible for the multiplicity and inferior quality of some of our medical schools. With proper state regulations institutions unable to offer the requisite amount of bedside experience would of necessity go out of existence. The hospital is the most important part of a school of medicine, and that school which does not own or, to some extent, control a hospital sufficiently large to furnish practical experience for its students is not only incomplete, it is a pernicious and dangerous institution. It is greatly to be hoped that state or national laws, as well as the force of enlightened public opinion, may soon remedy the evils caused by the existence of such establishments.

3. As a matter of fact, however, most even of our larger and better supplied institutions do not, as they should, own or wholly control the hospitals on which they depend for clinical material, and the vague fear that the admission of students to the wards may prove prejudicial to the interests of patients or institution deprives these schools of an enormous amount of valuable material. That this fear is wholly without foundation is a fact which is clear enough to any one who has had experience with active ward teaching. But there is another side of the question, to which attention has recently been called by Dr. Osler,* which is of very great importance to the hospitals themselves. The duties of the house physician with the recent advances in methods of precision in diagnosis and study of disease in ward and laboratory, have in latter years increased to a degree that demands outside assistance if the patient is to be properly studied, properly watched, properly treated. Much of this work can be done better by advanced students than by any other class of assistants. To assign three or four advanced students as clinical clerks to a ward of twenty-five or thirty patients, letting each student be responsible for the history, the examination of the secretions, the general observation of four or five patients, under the control of the ward physician, is to give the physician invaluable assistance in the keeping of records, in accuracy of observation, in the detection of many points in the progress of the disease, points which may be, and often are, of vital importance to the patient. The admission of students to the wards of hospitals in this capacity is not only without harm to the patient but is of the greatest practical value. That the careful study of each case resulting from such a system is, moreover, without annoyance to the patient I can testify from my experience of the past thirteen years in Professor Osler's wards, in which I have seen the direct transition from one system to another. To the student this experience is invaluable, and it seems to me to be absolutely necessary, if the degree of doctor of medicine is supposed to represent a qualification for practice.

Such experience, however, is of limited value unless it be associated with frequent and careful ward visits from the instructor. And these visits make considerable demands on his time. Teaching, direction of the research work of the department, the study of the material afforded by the clinic, these should be the main duties of the professor of medicine—duties incompatible with other than a purely consulting practice. To make this possible our universities must recognize the fact that the professorship of medicine, as well as the professorship of anatomy, should be properly endowed. Only by the adoption of some such system as this can we hope to bring our instruction in the practice of medicine to the level of that which is given in Europe.

For proper ward teaching the clinic must be so organized that the professor shall have several regularly appointed assistants, who shall take part in the investigation and instruction going on in the department. This is desirable, not only for the instruction of the students, but for the education of teachers. If we are to approach the infinite number of problems in pathological physiology which come before us every day in the observation of disease in anything like the manner in which such problems in normal physiology are studied in the laboratory, we must have a regular staff of assistants. No laboratory of physiology, for instance, could accomplish scientific work if the entire staff consisted of the professor and a number of young internes appointed annually from the graduating class. It is only through the opportunities offered by such positions that younger men are enabled to acquire that experience which fits them for the task of teaching.

The problems involved in the study and teaching of clinical medicine differ in no essential from those connected with the study and teaching of physiology, and until we recognize this fact and meet it squarely our clinics will remain unproductive and our teaching inadequate.

The most serious impediment in the way of advance in our methods of clinical study and teaching is the wide-spread institution of rotating services in our hospitals. In no service where the head of the department changes every three or four months can really valuable investigation be accomplished. And the best instruction can not be given to students in wards presided over only by a visiting physician and young, annually appointed, assistants. A permanent service, even though it be small, and a fixed staff of assistants offer incalculably greater advantages for study and research and teaching.

It is, of course, evident that instruction of this sort in larger schools can not be given in one clinic or by one man. The day must come when every well equipped hospital shall be at the same time a laboratory for the study and teaching of clinical medicine, offering the clinical advantages required by the central university or by state regulation. Every physician or surgeon holding an appointment at a large hospital or out-patient department should be encouraged to teach.

The hospital will gain by the supply of the best trained assistants and by the education of the staff, for there is no training so good as that of teaching, and there are no such spurs to work and progress as the questions and suggestions of the enthusiastic student.

The student will gain, in a few months, experience which it might require years to accumulate after graduation, and he will acquire that experience, as I have said

* Med. News, N. Y., 1903, lxxxii. 49.

elsewhere, at a time when he is free from the prejudices and preconceived ideas which are sure to obscure the judgment of the man who has gained his medical experience second hand from books or lectures.

The general public will gain the simple protection which any civilized government owes its citizens.

In this very city there are opportunities such as exist in scarcely any other community of this country for the realization of our ideals in medical instruction—a city of over 300,000 inhabitants, a fine old hospital of nearly 900 beds, a single school connected with a university of honorable past and most promising future. Tulane University has been a leader in this branch of medical education, but it can do more. The university can still offer to the hospital and the hospital to the university that which might make New Orleans the model for the rest of the country.

Original Articles.

THE BOY'S VENEREAL PERIL.*

[The author believes that the objects of this paper will be furthered by substituting initials for his name and by omitting his address in reprints thereof.]

FERD. C. VALENTINE, M.D.
NEW YORK.

I. INTRODUCTORY.

Many important books have been written and many valuable papers contributed to medical journals on the dangers of venereal diseases. All show that venereal diseases are more perilous to the individual, the family and the state than are all other ailments combined.

Study and effort directed to their abatement lead to the inevitable conclusion that venereal diseases are due essentially to prostitution, clandestine and public. The knowledge that venereal diseases are due mainly to prostitution does not, however, reveal the means of curing the evil: 1, Because all efforts to reduce public prostitution have proven and are always likely to prove futile; 2, because clandestine prostitution is necessarily beyond all efforts to limit its still greater power for evil.

The principal cause for the physical and moral wrecks produced by prostitution lies in ignorance. The same ignorance misleads many of the victims of prostitution to regard lightly the ailments thereby acquired.

The need for public enlightenment being manifest, many earnest men, I among them, have advocated lectures to the people on these subjects. More mature thought has, however, brought the conclusion that such lectures would fall short of their purpose, principally because, to be effective, instruction must be given at the opportune moment. A state of receptivity dependent on a condition so individual as mental, physical and sexual puberty must necessarily, in any assemblage, form as varying a factor as there are people present.

Obviously the effective teaching of these matters can be done only in private. It would seem at first glance that this is the father's duty. But some, indeed many men are so far removed psychologically from those nearest them that they could never successfully undertake this delicate task. Such men must relegate the duty to the physician, the teacher or the clergyman.

Among teachers and clergymen many have vague, and often gravely erroneous ideas on these subjects. Indeed, a majority of them has not received even rudimentary education on the structure and functions of the genito-urinary organs. They consequently have no knowledge whatever of the diseases due mainly to misuse of the genesic function.

If, for the reasons given, the father, clergyman or teacher is disqualified from imparting the necessary warnings, it may be well to direct the youth to study the third, fourth and fifth divisions of this paper.

II. THE DANGERS OF VENEREAL DISEASES.

In occasional contributions to our medical journals one eminent man or another asserts that the exercise of the sexual act is unnecessary for the preservation of health. As far as I know this has not been refuted. One reason for this silence may be, and probably is, that such refutation would be more likely to be read than were the articles contested. They would, as all such things do, fall into the hands for which they are least intended and be perverted to serve as scientific endorsement for libertinage and profligacy.

Wiser and deeper students may, in the course of time, establish whether illicit relations between the sexes is ever a vital necessity. For the present it suffices to say that young men are everywhere beset by temptations and induced by the spirit of evil, by the jests of their companions and by the solicitations of mainly clandestine offenders to seek sexual gratification, the desire for which is thus awakened.

The present purpose would not be advanced by a discussion of the need of sexual gratification for the maintenance of health. Moreover, the subject seems too individual for generalization and therefore not capable of wide application.

So much, however, experience shows, that no matter what volumes may be written on the wisdom of male sexual purity, whatever the endeavors of moralists, there will be, as there always has been, a vast majority who disregard precepts which oppose their desires. In consequence there is, as there always has been and will be, an overpowering multitude of men who acquire venereal diseases to the detriment of themselves, their families and the state.

To what extent this detriment goes is incalculable, as statistics on the subject can not be reliable. It will suffice here to note that conservative authors estimate that one-eighth of all the patients in the hospitals of New York are inmates thereof because of venereal diseases or their consequences.[1]

Those in hospitals represent but a small fraction of the people attainted. The latest study of the question[2] made by a body of physicians appointed by the New York County Medical Society for the purpose, makes the appalling declaration that 200,000 people infected with venereal diseases are walking the streets of our city.

The working and consequently earning power of these people is materially reduced. If every infected person loses only $1 per day, then the loss of earnings from this cause alone amounts to *sixty million dollars* per year. This loss is directly or indirectly borne by all, even those who are so inexpressibly selfish as to have no feeling for the sufferings of others.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

1. Specific mention of the works of such eminent writers as Morrow, Sturgis, Tarnowsky and others, is intentionally omitted here because they are well known to the medical profession. Laymen who may desire further information on these subjects, can easily obtain from their physicians the titles of the best works that treat of them.

2. Morrow: Report of the Committee of Seven on the Prophylaxis of Venereal Diseases in New York City. Medical News, No. 25, 1901.

The heaviest part of the burden rests on physicians, who must give their services gratuitously to over 66 per cent. of their patients. But they do not complain of their unrecognized philanthropy, nor do they advertise it. They exercise it as the most important part of their priesthood.

Men who devote their lives to the relief of misfortunes which bring the deepest woes, are daily astounded at the consummate ignorance that prevails among all classes regarding what is, from the nature of things, a generally tabooed subject. It is not only the uncultured, uneducated man who is the victim of unbridled passions; his cultured, educated and intellectual brother is equally and just as frequently unfortunate. There is no excessive charity in here using the word "unfortunate," for he is truly unfortunate and it avails nothing to consider him otherwise; nor is there any excessive optimism in the conviction that if all men could be informed of the dangers of venereal diseases, fewer would contract them, or having contracted them would neglect them as they now do.

Honest endeavors are continually made, especially by physicians, to enlighten the public on this subject. But their excellent counsel must ordinarily be limited to persons who have already acquired the disease, and for whom the topic has at the time absorbing interest.

The ignorance that prevails on these subjects is far-reaching in its effects. The patient, uninformed of the dangers to his health and life, generally does not seek early and radical treatment for the infection. More frequently still, associating venereal diseases with the only mention of them that has come to his notice, namely, in the advertisements of quacks, he consults one of these harpies or their congeners, the patent-medicine dealers. Later on, and often too late, he learns that every community has conscientious practitioners who scientifically study these diseases. Only then does he discover that he has wasted time, injured his health and imperiled his life through his ignorance and the shamelessness of those who have taken advantage thereof.

As little as the patient knows of the dangers to himself of venereal diseases, so little is he aware of the menace to his family. He should know at least two facts, which in efforts laid before the profession were elsewhere discussed. These facts are:

1. That of all women who die of diseases of the reproductive organs, 80 per cent. are victims of gonorrhea, of which their husbands imagined themselves cured.

2. That of all children born with seeing eyes who became hopelessly blind within a few days after birth, 80 per cent. lost their sight because of infection by gonorrhea, of which the fathers imagined themselves cured. (This paragraph refers to the time before the Credé method of protecting children's eyes at birth was employed.)

The patient is, as a rule, as ignorant of these frequent results as he is of the danger which venereal diseases are to the community. The need, therefore, of instructing the people at large on these subjects is manifest. As said before, however, the knowledge usually is imparted after the damage is done.

Many physicians, I among them, have striven to aid in combating this most dangerous ignorance. Although the papers written were received in a most cordial and kindly fashion, they could not meet the fundamental defect which prevails, that of preliminary education in those whom physicians must instruct. This shortcoming was made painfully apparent by letters from practitioners in all parts of the country.

Manifestly, then, there is need for explanation to the young which will appeal to them at the most susceptible age, that of puberty. To meet these evident requirements I have, at various times, attempted to construct an essay that would serve the ends in view. But at almost every line I was confronted by the dread that, by the very writings, the youthful mind might be directed to temptations that might not otherwise come to it.

It was my fortune, at the second conference for the Prophylaxis of Venereal Diseases, held at Brussels early in September, 1902, to receive a copy of Professor Fournier's article addressed "To Our Sons When They Have Reached Their Eighteenth Year." This admirable paper, written temperately, with much wisdom and great tact, indubitably meets the requirements of the sons of intellectual people. The temptation at once presented itself to translate Professor Fournier's paper, but throughout it is permeated with the spirit which makes it so eminently acceptable to the French line of thought. It would not apply as well in our own country, where the Anglo-Saxon manner of thinking and living predominates. Appreciating the need of a similar effort it is now attempted in the hope that better pens will take up the matter for the benefit of the rising generation.

The proposition, as suggested before, involves the problem, at what period of the young man's life this information should be imparted to him. Those closest to him must be the judges of the opportune moment.

The remainder of this paper consists of:

1. The evidences of awakening genesic tendency.

2. Masturbation and the impulses or defects that lead thereto.

3. The evil influences that mislead youths into immorality.

4. Prostitution, public and clandestine, and the mental and physical destruction they bring.

5. Gonorrhea, chancroid, chancre, and their sequelæ.

6. Advertising quacks, nostrum venders and an exposé of the methods they employ to swindle those afflicted with real or imaginary genitourinary and other ailments.

7. The reasons why a youth with a real or fancied illness due to immorality should consult a physician whom he knows, or whom his father knows.

8. The reason why reputable practitioners do not advertise.

These matters, being addressed to boys, are necessarily presented in such elementary outline and puerile language that they have no place in a scientific publication. The author therefore requests their omission here, but for completeness will add them to the reprints of this article, which will be furnished to physicians on request to that effect.

31 West Sixty-first Street.

DISCUSSION.

DR. JAMES J. WALSH, New York—The great universities of Europe, especially those in Berlin, have deliberated on this question, and the students are taught what is meant by venereal diseases and what their significance is. This is certainly not a pleasing question for deliberation, but it is an exceedingly important one. At the University of Berlin a course on the significance of venereal disease, open to all the students, is supported out of the emperor's purse, and is very largely attended, thousands of young men attending such lectures. The time must come, and shortly, too, in America when the universities do something to protect the students and give them this much-needed knowledge. At the present time all

the universities are necessarily situated in the large cities, and the young men from the country are invited to come to the city, where they meet with the dangers of city life. I think it is our duty to give these young men such knowledge as will protect them against the physical evils of venereal diseases. Faculties which do not make some provision for this are neglecting a serious duty. Any objections to such a course being instituted in our universities are founded on pusillanimous prudery.

DR. F. W. ROBBINS, Detroit—I think the paper is written in a strong style and will impress the readers. I think that mental impression is of more importance to the youth than the mere knowledge. It seems to me that the period of life at which the intelligent young are instructed in these matters is, in most respects, too late. There are two periods in the boy's life when he should be impressed with this knowledge: 1. The early period, which comes at the ninth or twelfth year. Children at this period can scarcely be expected to be much impressed with such a paper in which there is so much discussion. Then it is that the boy more particularly requires the attention of the father and not of the physician. 2. At a later period, when the boy goes to school, he should be given this knowledge. I believe it is an injustice to allow these boys to go without this precious knowledge. I think it is not so much the knowledge as the mental impression which keeps these boys moral.

DR. DELANCEY ROCHESTER, Buffalo—I am particularly interested in Dr. Valentine's paper because twelve or fifteen years ago I presented a paper on a similar subject before the American Academy of Medicine. I believe the proper time for giving such instruction to these boys is during the high-school period, and the best way of imparting this knowledge is by the proper teaching of physiology in the schools by physicians. The whole subject of physiology should be taught and not—as at present—only part, and that imperfectly. The truth should be taught; and that is that there are two great functions of the organism, namely, the preservation of the individual and the perpetuation of the race; that the functions of the various organs of the body are subsiduary to one or other of these great functions.

A thoroughly careful and competent teacher could show by the history of the complete separation of the sexes in plant and animal life that there has been developed the most beautiful in flowers and the noblest in animals. Time does not permit me to elaborate the scheme, but I thoroughly believe that physiology taught in this way would arouse in each one a noble respect for the human body in all its parts and a determination to do all in his power to develop a perfect human being and to keep it pure and holy. I believe that by careful selection of teachers physiology could thus be taught in the public schools.

DR. THEODORE POTTER, Indianapolis—My experience has led me to somewhat the same conclusions as Dr. Valentine has reached. There are two periods in the boy's life when such instruction can be given: 1. At the time of puberty, when the boy is at home under the influence and control of his parents and family physician; 2, when he goes to school or college. At this latter period he will look on such instruction as may be given him in a serious way. If I am allowed to differ with the last gentleman who spoke, I must say that I question whether the public school or the intermediate school will give the proper opportunity for giving such instruction, because the boy is more or less immature at that time and looks on such teaching as frivolous and makes a joke of it. Later he will listen and take it in a more serious way. When attempts have been made by public school teachers to instruct the boys in this country they take it as a sort of joke; but this is not so among the college students. It really is surprising what a great amount of ignorance is displayed by those young men who are entering or who have gone through college. I have had experiences in the west as well as the east in institutions, and I have seen the most lamentable examples of young men, not bad men at all, who have gotten into trouble largely through ignorance. This is the point: The young man goes free for the first time when he enters college and, since human nature is imperfect, when he reaches this time of freedom something goes wrong and it is largely through lack of proper instruction. I believe Dr. Valentine is right when he states that when the young men attend college, reaching the age of maturity, then is the time that serious instruction should be given.

It has been my habit, and this I think should be done by the physicians all over the country, to say to my patrons who have boys, that I am going to talk to a few boys at my house and if they wish they may send their sons. Invariably I have met with a willing response, and I know that my efforts have been crowned with success, so far as instructing them is concerned.

DR. M. M. SMITH, Austin, Texas—I desire to lay special stress on the influence exerted by the home circle in the prevention of venereal diseases in young men. During the earlier years of the boy's life he is constantly with the mother and if she is careful of his conduct and associates and watches him carefully and teaches him obedience and morality during these years, instead of spending much of her time at card parties or other amusements, when the boy runs loose about the streets during her absence, he will show the value of this watchfulness in his character. Equally important is the duty of the father, and especially is this true when the boy reaches the age of puberty. This is the time the father should be his companion and friend, and especially watch his conduct and companions and guide him safely over these few years when he is developing into complete manhood. A little denial of lodge meetings or the absence from clubs or other social functions will result beneficially to the boy's welfare in life. It is too often the case that the parents are earnestly at work to further some charitable and noble enterprise in that public-spirited manner; but at the same time they are neglecting their own children at a time when their influence will leave its effects all through their lives. The subject should engage the attention of the parent, the teacher and the physician; in fact, on the proper solution of the subject depends the future welfare of the nation.

DR. FRANK A. JONES, Memphis, Tenn.—I doubt very much the propriety of bringing this matter before the laity as advocated. By doing so there will be a tendency for the boy of young age, who is disposed to look further into such matters, to investigate further with disastrous results. We meet sexual neurasthenia which is purely an imaginative condition; many come to us with trivial affections and even talk of suicide, and this may be the result of publicity being given to such matters. I do not think this subject should be placed before the public. Try and enjoin on the young men this, that the way of the transgressor is hard. I think the young men can be reached better through the medical profession than through the public press or other means of publicity. I think it would be wise to distribute Dr. Valentine's article by the thousands to various physicians in the American Medical Association.

DR. E. L. STEPHENS, Des Moines—Before the boy reaches the age of puberty I think he should be taught the sacredness and naturalness of the sexual instinct, and this can be done in a quiet way. There has been published a book, "Almost Fourteen," by Mortimer Warren, which I think is most suitable to place in the hands of young men, and the only one that I have been able to find after nearly forty years' search.. That is, I believe, the only one that can be safely placed in the hands of young men as being scientific and pure. Since the American Medical Association has been reorganized we now have a means whereby we can legitimately place such information before the public; previously it could only be done by quacks. Now each councilor in each district has the privilege of using the public press for disseminating proper information. Why not take this opportunity for exercising this point? I would not think it proper, nor would I advocate placing posters in water closets, etc., but we can present through the public press the right ideas and the right information which would offset the wrong impressions given the laity by charlatans and quacks.

DR. WALTER SHROPSHIRE, Yoakum, Texas—I think that if anything is to be accomplished toward protecting the young

of this country it should be done at a time when it would be effective. When the boy reaches college it then is too late. If we should wait until some definite period we should select that period when such instruction would be most efficient and that is concomitant with the development of the sexual function in the boy. When he first learns of this function he should be taught the dangers of its misuse. I really believe that physicians should teach physiology in the public schools and, at the same time, they should teach regarding the sexual function and the dangers which its abuse entail.

DR. FERD. C. VALENTINE, New York—Naturally it was impossible in the brief synopsis which I presented to cover the entire ground; that has been largely done by the gentlemen who so kindly discussed my effort.

With regard to Dr. Walsh's remarks, I may say that the universities in Germany, beginning in Berlin with Lassar, have given instructions to students regarding the dangers, etc., of venereal diseases. Lectures are delivered to students of all the departments of the university. The brilliant success of Lassar was so encouraging that it caused an increase in the number of such lectures, with exceedingly good results. But you may ask how many of those young men who came there to be educated and were instructed in venereal diseases had not unfortunately educated themselves. In Berlin the war is directed against the repetition of contracting such diseases, as well as instructing regarding their nature and results. I agree with Dr. Walsh, that some method should be introduced in this country to teach the young men the evils of venereal diseases. I wish to emphasize his remarks and say that university students who attend these lectures derive much benefit at the time when they certainly are qualified to receive such instruction.

What Dr. Robbins says regarding the time for receiving such instruction is undoubtedly correct, but he says it is not so much knowledge but impression which is of value, and that they should be taught at an impressionable age. But what is that age? That varies with the individual. There are some boys who are impressionable at the age of 12. I am now treating one not quite 14 years old, who has a gonorrheal prostatitis. This boy is the only son, in a good family, and has been correctly raised. With six others he was solicited by a girl of 14; all six contracted gonorrhea. Had he been instructed at the period when he was of the impressionable age his misfortune might have been averted.

FAT NECROSIS OF THE KIDNEY.*

JAMES R. GUTHRIE, A.M., M.D.
Professor of Obstetrics and Gynecology and Dean of the Medical Faculty, University of Iowa.
DUBUQUE, IOWA.

When we consider the rather superficial location of the kidney, its importance and the various pathologic changes to which it is liable, it is strange that for so long a time it eluded careful examination and escaped the surgeon's knife. In the past five years, however, the surgeon has made determined, successful efforts to make good that deficit.

Fat necrosis in the tissues of the body is neither a new process nor a new discovery. It has long been recognized in the several tissues of the human body, notably in the abdomen, in the abdominal walls, in the subperitoneal fat, in omental structure and in the pancreas. For a long time it was supposed to be due to some form of pancreatic disease, but it is now well known to occur independently of any affection of that organ. The accepted physiologic view is that fat may be formed in both animal and vegetable bodies from albuminoid matters. Proteids break up in the body into nitrogenous and non-nitrogenous compounds. This is demonstrated in the human subject and by experiments on the lower animals. The non-nitrogenous compounds not being completely oxidized in the cells are formed into fat. The process actually occurs wherever fatty substitution takes place in the animal cell. Hoppe-Seyler takes the view that fat is not directly formed from albumin, but that glycogen is first formed and that fat is a resultant product. Volt's view, and the one generally accepted, is that fat is formed directly from proteid material. Graham Lusk,[1] after quoting various experiments along this same line, concludes, "It seems rational that in acute fatty metamorphosis of the cell that dextrose found may be quantitatively converted into fat."

The physiologic fact, I think, as well as the chemical changes underlying it, are reasonably well understood and generally accepted, but the etiologic factors, active and predisposing, are by no means clearly settled. Fat necrosis, as the term is employed in this paper, denotes a type of necrosis to which certain tissues are liable, separate and distinct from fatty degeneration. It presupposes the fact of fatty degeneration and, subsequently, a necrosis forming of the entire structure of fatty emulsion.

According to Stengel, there are a few microbes which form emulsifying ferments, which may cause this fatty emulsion. The term "liquefaction necrosis" probably better conveys the correct meaning. Ziegler says, "A liquefaction necrosis may occur in the tissues where the cell wall becomes dissolved in the fluid present in the part." "Fatty degeneration may so terminate," says this distinguished authority. Bacteria is said by some observers to be concerned in this change. The part played by these organisms is still under investigation. Dörsch says, "The cortex of the organ is most frequently involved, though the medullary portion is frequently affected in a minor degree." Hektoen considers this condition due usually to the escape of the fat-splitting ferment, resulting in the formation of fatty acids and lime salts. Gaylord states that fat in the kidneys occupies the space between the lobules in the connective tissue.

There are many causes assigned for the formation of a fat necrosis in the tissue, either with or without liquefaction:

1. Changes in the supply and composition of the blood.
2. Diminished oxygen.
3. Blood diseases.
4. Narrowing of the arteries supplying the part. (Narrowing of the blood vessels of the heart leads to fatty degeneration, according to Hektoen.) Fatty degeneration of the kidney in pregnancy is due to disturbed circulation, says Stengel.
5. Persistent venous congestion. Displacement of the kidney producing, as it certainly does, changed blood supply, diminished oxygen, torsion of the renal artery and, together with a constant venous congestion, is a sufficient cause for liquefaction necrosis of the organ.

In the literature which I have been able to examine the references to this subject have been sparse indeed. A case is reported by Dr. T. Charlewood Turner[2] of a girl 13 years old who died of pericarditis. The autopsy revealed a fatty kidney, and he described a necrosis with softening and, though it is not distinctly stated that the necrosis affected the fatty tissue, yet from the present light I think this a fair presumption, that the

1. Report before the American Physiological Society, Boston, Tenth Annual Meeting.
2. Transactions Pathological Society of London, 1886.

softening was due to a liquefaction necrosis in the fatty substance.

Dr. Ephraim Cutter,[3] New York, contends that many organs of the body are subject to fatty substitution, and that necrosis of this fat is often present.

E. W. Cushing[4] describes the case of a patient who passed urine, one-fifth of which was oil, several days before death, and that among other things the post-mortem examination revealed a necrosis of fat about the kidney, producing oil which escaped with the urine.

Thomas Oliver[5] reports, from his private practice, two cases of oil in the urine. He asserts that there was present in these cases a fat formation and a tendency for molecules of fat to form into globules, which, by solution of the cell wall, made their escape into the pelvis of the kidney. There is evidence enough to establish the possibility of oil formation in the structure of the kidney itself. Newbaur, in his work on the urine, speaks of the rare appearance of this constituent in the excretion derived from the kidney from this fatty substance. Fat globules are held in solution by the albumin present. Roberts, in his work on urine and urinary disease, may also be quoted to the same purpose.

It is believed, therefore, that a liquefaction fat necrosis is possible in the substance of the kidney; that a dislocation of the kidney may form the active cause for this change, and that the case briefly described below falls under this category.

April 23, 1902, I was consulted by Miss M. D., aged 22, of Welsh parentage, with unexceptional family history and personal history, free from disease, except some slight illness in childhood. She gave a history of a tumor-like mass, discovered by her about one year before, in the left hypochondriac region, extending down to two inches above the umbilicus. The November previous she consulted her physician, who found the enlargement, which he described at that time as freely movable, and made a thorough examination of the patient, with a negative result, except that he found general loss of strength and great languor. Her symptoms remained practically unchanged, except increased weakness, which led her to seek further assistance. She entered the hospital on the afternoon of April 23, and the examination which I made the following day resulted negatively, except that there was an accelerated, weakened condition of the pulse, and a tumor located as above described. The tumor seemed to be nearly one-half larger than the normal kidney, and by pressure could be returned nearly to the normal kidney location.

April 25, a lumbar kidney incision was made in the usual manner, and the kidney brought up into the wound and the fibrous capsule grasped by a clamp. The capsule gave way and there was discharged from the kidney a yellowish semifluid substance to the amount of 12 to 14 oz., and resembling in color an emulsion of cod liver oil and iodoform, containing a peculiar flaky or shredded material. By digital examination I found that, practically, the whole kidney substance had been destroyed. I stitched the kidney into the wound, leaving free and unobstructed drainage. Some of this semifluid material drained from the kidney for several days. Some of the material saved in the test tubes I submitted to Dr. Geo. Mengis, Dubuque, Iowa, for chemical and microscopic examination, and he reported the material composed almost entirely of an emulsion containing oil, fatty cells, together with fibrous and connective tissue. A fatty substitution had taken place in the kidney, followed by liquefaction necrosis, which had, practically, destroyed its secreting structure.

It is believed that this girl primarily suffered from a floating kidney, which, by torsion of the renal artery, produced the pathologic changes described. The recovery following the operation was uneventful, with the exception that for three or four months she suffered from weakness and rapidity of the heart's action.

In a letter received not long since from her physician, Dr. C. W. McLaughlin, Washington, Iowa, I learn that she has completely recovered. The sound kidney seems to be doing well the work of elimination.

SURGICAL TREATMENT OF NEPHRITIS.*

ALEXANDER HUGH FERGUSON, M.D.
CHICAGO.

"The Surgical Treatment of Nephritis or Bright's Disease" was the title of a paper published by me March 11, 1899, in THE JOURNAL of the American Medical Association. This is the first announcement that has ever appeared recommending a surgical treatment for Bright's disease. The date of this publication has been overlooked by Dr. G. M. Edebohls in all his articles. Dr. Edebohls' first paper, entitled "Chronic Nephritis Affecting a Movable Kidney as an Indication for Nephropexy," appeared in the *Medical News*, New York, April 22, 1899, one month and eleven days after my first article.

Feb. 10, 1899, a symposium on nephritis was the program of the Chicago Academy of Medicine, and the surgical treatment was assigned to me. At this meeting I related two cases of interstitial nephritis symptomatically cured by *decapsulation and multiple punctures*. I removed a portion of the kidney in each case, which was pathologically reported on by Drs. Klebs and Zeit, and they pronounced it interstitial nephritis. In these two instances no positive diagnosis was made before operating.

At that meeting I related several earlier cases, but inasmuch as I had not examined a section of kidney tissue microscopically in any of them, I thought it wise not to publish anything but the two cases in which that was done. Dr. R. B. Preble, while denouncing splitting of the capsule, etc., as dangerous and useless, terminated his remarks as follows:[1]

While Dr. Ferguson's paper was interesting, still the bulk of the cases do not apply to nephritis at all (claiming that my diagnoses were in error), and the latter cases which were demonstrated to be nephritis have not recovered from their nephritis, but have been relieved of a purely subjective symptom.

Time has proven him to be wrong.

HISTORY.

In 1902 an article from the pen of Guiteras,[2] on the "Surgical Treatment of Bright's Disease," gave an excellent historic review of work leading up to this subject. He, too, overlooked my first publication, March 11, 1899. He gives the more recent developments, and has added three cases operated on by himself. It is my intention in this short paper to briefly give the evolution of the surgical treatment of nephritis, and add a few more cases of this disease treated surgically.

Reginald Harrison made a mistaken diagnosis in three kidney cases (1878, 1887 and 1893) of an abscess in one and stone in the other two. He cut down on them and found acute nephritis instead. It was fortunate for his patients that he and his associates were in error,

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

2. New York Medical Journal, May 17, 1902.

for the operation cured them, and let me ask if in these cases a diagnosis of acute nephritis had then been made. would the knife have been recommended? I think not!

Newman (1896) observed in two cases the beneficial influences fixation of the kidney had on albuminuria. In 1899 Tiffany successfully incised the capsule and parenchyma of a kidney affected with chronic nephritis, complicated with nephralgia. In 1886, Péan removed a kidney for nephralgia and chronic nephritis.

In October, 1899, Pousson collected 25 cases and added 2 of his own; of hematuric nephritis, 10 cases; nephritis with nephralgia, 2 cases; subacute infectious nephritis, 4 cases; acute infectious nephritis, 9 cases. The kidney was removed in 11 of these, opened in 13, and 1 exploration, with 21 reported cured. These operations mentioned by Pousson included those of Harrison, Weir and Israel, and were undertaken, not with the object of curing Bright's disease, acute or chronic, but for some suspected surgical condition, such as abscess, tumor, stone, etc.

In 1899 Israel reported 14 cases of hematuria and nephralgia treated by nephrotomy. In 12 of these there was evidence of chronic nephritis. It must be remembered that Israel did not aim at a surgical treatment for Bright's disease, and recommended an operation only when there was hematuria or nephralgia.

In November, 1890, Naunyn, in writing of nephrotomy for bleeding in nephritis, stated that "nephrotomy may some day play a far greater rôle in the treatment of Bright's disease."

Edebohls, April 22, 1899; 1901, and 1903, has given to the medical world his conceptions of the surgical treatment of nephritis, his operations and results. I wish here to commend that work. He observed the beneficial effects of nephropexy eleven years ago. "My first case was operated on as long ago as Nov. 29, 1892; my fifth April 1, 1897."[3] In speaking of his sixth case, in the same article, he says: "This operation, performed on Jan. 10, 1898, constitutes the first operation ever undertaken on the kidney with the deliberate purpose of curing chronic Bright's disease and, in so far, marks a period in the history of the affection." This case was published in his first paper (April 22, 1899), after my first publication.

Dr. Edebohls' work has taken root, and we are here and there hearing of good results from other surgeons. Physicians in the first rank recognize that there is a surgical treatment for nephritis. To Dr. Edebohls is due the credit of individually working out this surgical treatment and operating on more cases of Bright's disease than any other surgeon. While I am constrained to claim priority (first in publication), I can not but feel proud of the distinction and record the Doctor has made for himself in trying to solve the limitations of kidney decapsulation in nephritis. Dr. Edebohls'[4] published experience amounts to no less than 51 cases treated by operation. It will be seen in the description of my experience, our work has been developing contemporaneously.

I shall now very briefly refer to the development of kidney surgery before giving my personal work on nephritis. It is only thirty-five years since the kidneys have been operated on at all. Like many of the other internal organs of the body, diseases affecting them were treated by internal medication. We can appreciate how Peaslee (1868) felt when he removed a kidney by mistake, taking it for a solid ovarian tumor. Although the patient died on the third day of peritonitis, two lessons have been learned by his mistake. First, the feasibility of nephrectomy, and second, that urine was secreted abundantly by the other kidney. Spencer Wells' case also died, but not from suppression of urine.

The following year (1869) Simon of Heidelberg purposely and successfully attacked the kidney for a ureteral fistula in a woman. I have no doubt that his experiments on dogs in this line better fitted him to successfully perform the operation.

Within seven years after the first removal of a kidney by Peaslee, no less than 233 nephrectomies were collected by Gross (1885). It would take some considerable time to reckon the number of nephrectomies up to date. The operation was extended beyond its reasonable and legitimate limits. Chief among the indications for the removal of a kidney were stone, pyonephrosis, hydronephrosis, tuberculosis, floating kidney, nephralgia, hematuria, and tumors.

Nephrotomy for stone (nephrolithotomy) was first performed by Morris of London only twenty-three years ago (February, 1880). Then nephrotomy gradually supplanted nephrectomy in many cases.

Nephropexy, by Hahn (1881), was the next important advance in renal surgery.

PERSONAL EXPERIENCE.

In 1899 I explored a kidney suspected of containing a stone, in a young man, 24 years of age, suffering with renal colic. There was blood in the urine, and the kidney was very tender on pressure. The exploration consisted in exposing the organ and passing a darning needle, blunt end foremost, through it in many directions. No stone was found, but temporary relief from pain and hemorrhage was given. Within a year afterward he returned to see me. Bright's disease became more and more marked, and four years afterward he died of parenchymatous nephritis.

In my early fixation of floating kidneys, I used a stout chord of chromic catgut and passed it through them four or five times and, while using this stout cord, no complaints came from our patients after the operation. But just as soon as we began to use fine catgut or silk and grasp only the capsule two cases returned, complaining of pain, as before, although the kidneys remained fixed. In 1900 I explored one of these for stone with the knife; found nothing; had free hemorrhage, which was checked with iodoform gauze. This made a symptomatic cure; the nephralgia completely subsided, and she is now well. After this I did some fixations by cutting through the capsule, rolling it a little to each side, and passing sutures through it and through kidney tissue as well, with satisfactory results.

My first decapsulation, deliberately undertaken, was for "Nephritis and Floating Kidney."

NEPHRITIS AND FLOATING KIDNEY.

CASE 1.—*History.*—June 17, 1896, Edna L., aged 25, entered the Post-Graduate Hospital complaining of a painful, tender, floating and enlarged right kidney. Urine scant, ℥xx in twenty-four hours; contained 30 per cent. albumin.

Operation.—Nephrorrhaphy; capsule stripped off. Urine increased in quantity, and albumin decreased. Nephritis was diagnosed as a complication. Case lost sight of (hospital record).

DOUBLE DECAPSULATION FOR NEPHRITIS AND FLOATING KIDNEYS.

CASE 2.—*History.*—Sept. 9, 1897, Mrs. B. G., aged 30, entered the Post-Graduate Hospital complaining of pain in the region of both kidneys. She had been suffering for twelve years, particularly from her right side. She was operated on three years previously for ovarian abscess, and one year previously (in

3. New York Medical Record, Dec. 21, 1901.
4. Medical Record, March 28, 1903.

1896) for right floating kidney. Had one child twelve years of age. Her father died at 30 years of consumption. Her urine was very abundant, pale, and contained a trace of albumin. She was considered hysterical. Interstitial nephritis diagnosed. Both kidneys were floating freely.

Operation.—Capsule stripped from both kidneys, and sutured to lumbar fascia. She made a good recovery, and marvelously improved. Within six months she was able to do all her housework.

No cure was expected in this case, decapsulation being performed with the object simply of relieving her pain and tenderness. She was, two years later, symptomatically cured of her Bright's disease. It then occurred to me that all cases of tender and floating kidneys were cases of interstitial nephritis, and from this date (September, 1897) I expressed my convictions at my clinics.

MICROSCOPIC EXAMINATION OF KIDNEY TISSUE FOR THE FIRST TIME. LEFT FLOATING KIDNEY; INTERSTITIAL NEPHRITIS (BRIGHT'S). DECAPSULATION AND PUNCTURE.[5]

CASE 3.—*History.*—Mrs. M., 37 years of age and weighing 250 pounds, entered the Post-Graduate Hospital complaining of just two symptoms; (*a*) Dizziness, and (*b*) pain in the region of the left kidney. Taking morphin for the pain. Ill for three years. Began to have these symptoms after childbirth. Urine scanty, ℥xxiv in twenty-four hours. Normal, except a few hyaline casts.

Operation.—Jan. 4, 1899, I decapsulated the kidney, made multiple punctures in it, fastened it up, and removed a portion for examination. The immediate relief was astonishing to us all. Even the next day she declared that she was free from her old pain.

Pathology.—Microscopic examination of kidney tissue revealed interstitial nephritis.

In 1900 she returned, complaining of pain in her pelvis, and through the vagina I removed a left ovarian cyst. At this time her urine was normal in quantity and quality, but occasionally, such as after a hard day's work, she had an aching feeling in her left side, for which electricity was used. I have heard from her repeatedly during the past year, and she is symptomatically cured, it now being over four years since the operation.

INTERSTITIAL NEPHRITIS (BRIGHT'S); RIGHT FLOATING KIDNEY. DECAPSULATION. NEPHROTOMY (DRAINAGE); NEPHRORRHAPHY.[6]

CASE 4.—*History.*—Mrs. W., aged 26; chronic pain over right kidney, which was freely movable. Was taking from two to eight grains of morphin per day for the pain. (See full report.[6]) Had two confinements, one miscarriage, pulmonary hemorrhage, trachelorrhaphy, chills and fever (supposed to be malaria), cholecystotomy.

Operation.—Finally I operated on her right, tender, floating kidney. Owing to the septic condition of her urine, I thought the kidney was septic also, but it was not.

Pathology.—Microscopic examination of kidney tissue revealed the unmistakable changes of interstitial nephritis.

The immediate result was admirable. The albumin and casts cleared away before she left the hospital. After the first three days after the operation, she did without morphin, even though a habitué. Two years later she was well, and a later report brings the same good news.

INTERSTITIAL NEPHRITIS; NEPHROTOMY AND DRAINAGE OF LEFT KIDNEY.

CASE 5.—*History.*—Mrs. H.; aged 32. From Livery City, Iowa. Complains of pain and tenderness in the region of left kidney, which began two years previously, and then lasted severely for twelve hours, and had bloody urine. During 1897 and 1898 she had several attacks of pain and tenderness, referred to her left kidney, sometimes passing blood in urine, and often accompanied with chills and fever. During the last six months the attacks were more frequent, but no blood was passed with the urine. Mild chills and feverish sensations accompanied nearly every attack. On going over the case thoroughly, a diagnosis of recurrent interstitial nephritis was made.

Operation.—Nephrotomy was performed March 16, 1899, and kidney drained for twelve days. Patient left the hospital after three or four weeks, with marked general improvement, and entirely relieved of her pain and tenderness over the kidney.

Pathology.—The microscope shows interstitial nephritis.

INTERSTITIAL NEPHRITIS (LEFT). DECAPSULATION AND MULTIPLE PUNCTURES. GAUZE AND TUBE DRAINAGE TO KIDNEY.

CASE 6.—*History.*—Mrs. C., aged 43; dressmaker. In August, 1898, frequent urination; pain in back and over left kidney. Urine contained blood, albumin, casts; was highly colored and scanty, as reported by her attending physician at that time. Ever since this attack, kidney has been tender, but the urine has become abundant, three or four times the normal quantity, of low specific gravity (1,005), and always contained albumin and usually casts. Menstruation began at 14 and has been irregular. Edema of feet and hands; eyelids swollen and eyesight poor. Had pneumonia three times; inflammation of the bowels twelve years ago (probably appendicitis); abscess (1893) in pelvis opened into vagina; gonorrhea from her husband fourteen years ago (1885). Her mother died of ovarian tumor and interstitial nephritis. The region of the left kidney was tender.

Urine segregated, and that from the left side showed the following changes: "The specific gravity of both specimens is so low that I thought a mistake had been made, and we got water for examination. Doubting whether this was urine at all I tested for urea, and found 0.2 per cent. in both urines (should be 2 to 3 per cent.). There are some chlorids and phosphates, but the centrifuge shows no sediment of any kind, except a few squamous epithelial cells and oil globules in both specimens. No albumin; no sugar in either specimen. Reaction: Neutral in both specimens. No bacteria found in either urine. No casts." (Zeit.)

Pathology.—Report of kidney tissue: Interstitial nephritis.

Operation.—June 28, 1899. Left hospital in twenty-three days, improved in all her symptoms. In three months, urine much improved. Symptoms of nephritis almost absent. At the end of six months she resumed dressmaking. Her gain in general was slow, but gradual. During 1900 she had to cease working for a week out of every six or eight. In November, 1902, she was confined to bed for two weeks, and house for three weeks longer, with influenza. Both kidneys were sore and tender, but fortunately no active inflammation of them manifested itself. It was fully four months before she regained her usual health. Now she replied: "I am well; that is, much better than before the operation. I am working all the time, but have to be careful But I enjoy life. It makes me feel happy that for six months there has not been even a trace of albumin in my urine."

NEPHRITIS. DECAPSULATION.

CASE 7.—*History.*—Mrs. D., Redland, Iowa. Post-Graduate Hospital. Aged 34. Complains of: 1. Constant pain in the region of right kidney, with some pain in the left, off and on. 2. Inability to work for the last two years. 3. Urine irregular in quantity. 4. Shooting pains into back and thigh. Pain often severe all night, and during the day it is increased on motion. 5. Is weak, dizzy, constipated, and is troubled with palpitation of the heart.

Had a child two years ago, and has not been well since then. When 15 years of age, was struck in the right inguinal region with a baseball, following which she had colicky pains in that region for some time. Family history negative. Urine too abundant, ℥cxvi in twenty-four hours, of low specific gravity, 1,005; a trace of albumin; no sugar; casts, granular, hyaline; and contained indican. A diagnosis of interstitial nephritis was made.

Operation.—Decapsulation of right kidney. At the end of the third week urine in quantity only ℥xlv in twenty-four hours, and much freer from casts. (Portion of kidney removed was lost in the operating room.)

The patient left the hospital on the twenty-third day, free from her painful symptoms. Recent report not given. A

6. THE JOURNAL A. M. A., March 11, 1899.

year after the operation she was symptomatically relieved, and felt that she was cured.

MOVABLE KIDNEY AND NEPHRITIS. DECAPSULATION; MULTIPLE PUNCTURES.

CASE 8.—*History.*—Mrs. J. E. B.; aged 45; married. Admitted May 7, 1901; discharged July 2, 1901. Housewife; Swedish. Diagnosis: Movable kidney and nephritis. Parents both died from some acute lung trouble at an advanced age. Has seven brothers and sisters living and well. Patient has always been well. Married at 39; no children; never pregnant.

Present Illness: About five years ago she noticed pain in the right side of the abdomen, above the crest of the ilium and in back. About one year later she discovered a lump in the right side. It was easily movable in any direction, the limit being the center of the abdomen, costal cartilages, and below to McBurney's point. Has no severe pains at this time. Has worn elastic bandage for some time. Was able, but with difficulty, to attend to her household duties. For the last six months a dull, aching pain in the region of kidney has been constant. Menses now regular and normal. Bowels constipated. Lost some weight.

Operation.—Placed patient in saddle, which brought the kidney well up to parietes. Incision four inches long. Stripped kidney of its capsule. Made multiple punctures and anchored as usual. Drainage of gauze in wound.

Urine examination: Before operation, specific gravity 1018; acid reaction; slight albumin; hyaline and epithelial casts; no sugar. Temperature before operation, 98 to normal; pulse before operation, 80. Temperature after operation, maximum, 101; pulse after operation, maximum, 110.

Result: Dr. E. M. Brown saw the patient December, 1902. She was then entirely well.

PARENCHYMATOUS NEPHRITIS AND STONE. DECAPSULATION AND NEPHROTOMY.

CASE 9.—*History.*—Mr. F. R., aged 38, of Luther, Ind., entered the Post-Graduate Hospital June 26, 1901. Complained of (*a*) pain in left side, running down to the testicle; (*b*) attacks of sharp pains, laying him up; (*c*) urine scanty and high colored. He passed gravel a year ago, after an attack of renal colic; then got some relief. The last few months the attacks have been more frequent, and recently the pain in the region of the kidney has become constant. The urine contained pus, blood, casts, bacteria, albumin, increase of chlorids and some bile.

Operation.—Decapsulation was made, because the capsule was firmly adherent. Nephrotomy was then performed, and several small calculi removed. Removed a section of the kidney and drained the kidney with a tube. This tube was left *in situ* until the discharge was free from pus and germs. He made a good recovery, left the hospital July 19, 1901, free from pain and greatly improved in his general health.

Pathology.—The report of tissue by Zeit and Klebs was that of parenchymatous nephritis, with cloudy swelling, regenerated epithelium, with granular and epithelial casts in tubes.

Result: Both immediate and remote, excellent.

RIGHT FLOATING KIDNEY; SUBACUTE NEPHRITIS. DECAPSULATION AND NEPHRORRHAPHY.

CASE 10.—*History.*—Miss H., single, aged 32; musician; American. Admitted April 16, 1902. P. and S. clinic. Discharged May 18, 1902. Condition improved. Examined by Dr. E. M. Brown, March, 1903. Well.

Family history: Father and mother living and well. Four sisters and one brother living and well. One sister died during confinement.

Personal history: Diseases of childhood. Always well until ten years ago; began to get pale and weak. Exhausted on the least exertion, also very nervous. Bowels constipated. Appetite fair. Uncomfortable after eating. Began menstruating at the age of 13 years. Always regular, but painful. Eight years ago had dilatation and curettement for painful menstruation.

Present trouble: About eight years ago the patient had a fall from horse, since which time she has noticed a lump in right side of abdomen, which is very movable. Also complains of pain in right groin and appendiceal region. Tenderness of gall bladder also.

Urine examination; On admission, color amber. Specific gravity 1012: Reaction acid. Albumin none. Sugar none. Epithelial and granular casts. Urates and mucus.

Operation.—Usual kidney incision; kidney brought up and stripped; anchored to fascia. One strip of gauze for drainage. Appendix found suspicious and removed.

Pathology.—Microscopic examination showed slight change in interstitial tissue and parenchyma.

Temperature before operation, normal to 99. Pulse before operation, 76 to 90. Temperature after operation, maximum, 101.06. Pulse after operation, maximum, 112. Recovery uneventful.

DISPLACED AND FIXED KIDNEY. DECAPSULATION AND NEPHRORRHAPHY.

CASE 11.—*History.*—Mrs. B., of Ashkum, Ill, aged 33. Referred by Dr. Ernest. Entered Chicago Hospital complaining of (1) pain in abdomen, especially on the right side; extreme tenderness on pressure; (2) intense pain, as if on fire, which patient insisted was the case; (3) great weakness, loss of weight and strength; (4) mental and constitutional condition much deranged.

Very unsatisfactory history, except that symptoms began after an attack of measles, followed by typhoid in February last, since which time patient has been gradually growing worse. In bed and unable to rise for over three months.

Physical examination revealed a firm, movable tumor, of the shape of a kidney, on a level with the umbilicus on the right side. This could not be returned to the kidney fossa. Urine: Specific gravity 1014; urea, 2.2 per cent.; albumin, peptone, indican, pus, epithelia, cylindroids and phosphates all present. Feces: No pus or blood, very fetid. Blood: Hemoglobin, 45 per cent.; red corpuscles, 4,500,000; leucocytes, 11,000; no Widal reaction.

Operation.—April 22, 1902. Exploratory incision down on tumor, which proved to be the kidney. All the abdominal organs examined and found normal. Incision closed. Lumbar incision made and kidney drawn up into it. Kidney congested and capsule thick and firm. Capsule stripped off and section of it and kidney removed for examination. Kidney sutured in place and drained with gauze and incision partly closed. Patient transfused, 1,000 c.c. of normal salt solution on table.

After-treatment: Patient given normal salt, one pint per rectum, every four hours for several days, and liquids *ad lib.*, by mouth. Pulse 120 and irregular. Temperature 102.8. During first four days patient had involuntary bowel movements, after which she began to retain normal salt and rectal feeding. Wound received daily attention and was kept clean.

On the twelfth day temperature was normal and pulse stronger and regular. Patient was able to be up on the twenty-seventh day, and on the thirty-eighth day following operation was able to be taken home.

Pathology.—Specimen normal, except for a few inflammatory cells. Present condition, patient in good health and well. Remarks: I fail to see what my operation had to do with her recovery. A. H. F.

RIGHT FLOATING KIDNEY. DECAPSULATION AND NEPHRORRHAPHY. GALLSTONES. CHOLECYSTOTOMY.

CASE 12.—*History.*—C. Hosp. Dr. McKibbon, referred. Miss F., of Kalamazoo, Mich., aged 24; stenographer. Complains of (1) pain in right lumbar region, aggravated by exertion; (2) some swelling of ankles and of eyes; (3) headache and nervousness; (4) loss of appetite, constipation.

Illness began two years ago with pain in right side, which extends up to shoulder and down right leg. In February last it became worse and patient is now in almost constant pain. Urine: Specific gravity, 1024; no albumin nor casts. Epithelium (squamous).

Operation.—May 26, 1902. The kidney was found movable and prolapsed, and the gall bladder was palpable. Kidney decapsulated and punctured and sutured to lumbar wall. Gall

bladder drained after removal of stones from it and the cystic duct.

Kidney was drained for two weeks. Patient had temperature of 100 till the eighth day, when it rose to 104. This was accompanied by great nausea and vomiting. Wound was dressed. Stomach washed out and patient given hypodermoclysis, a pint and a half of normal salt and a pint per rectum every four hours. Temperature dropped to normal in two days, and patient made a good recovery, leaving hospital on thirty-second day with small sinus, which soon closed. Now satisfactorily relieved.

PARENCHYMATOUS NEPHRITIS. DECAPSULATION OF BOTH KIDNEYS.

CASE 13.—*History.*—Mr. B., aged 37. Referred by Dr. Wm. E. Quine. Complains of (1) pain in both kidneys, greatest in right; (2) highly albuminous urine; (3) general anasarca and ascites, with pitting over tibia on pressure.

When attending college about seventeen years ago patient contracted syphilis, for which he was treated three years and declared cured. Three years ago came to Chicago, suffering from anasarca, ascites and albuminuria. His life was despaired of, but by mercurial inunctions all symptoms except albuminuria cleared up. Patient was sent to warm climate, where he improved rapidly, stopped the treatment, grew worse, and under doctor's instructions began treatment again. Improvement now was slow and unsatisfactory. Recently patient has not been so well and was referred for decapsulation.

Right kidney is palpable and tender. Left kidney not palpable, but tender on pressing over it.

Urine: Twenty-four hours, ℥xxxii. Albuminous (50 per cent.). Granular casts in abundance. Pavement epithelia. Blood and bacteria present.

Operation.—Aug. 19, 1902. Right kidney exposed; the capsule, which was firm and adherent, was stripped off and the kidney punctured. Gauze drainage inserted down to kidney.

Patient made good recovery. Urine began to increase from the beginning, being ℥xli on the second day. The albumin likewise decreased, until on leaving on the eighteenth day there was only about one-half of 1 per cent. There was a slight fistula, which was rapidly closing.

Second Operation.—Patient returned Sept. 30 for operation on left kidney. Urine: Twenty-four hours, ℥xxxi. Albumin, 2¾ per cent. Casts: hyaline and granular. Left kidney drawn into wound and decapsulated. Drained down to kidney with plain gauze.

Patient made good recovery, leaving hospital on seventeenth day, with incision closed. Urine improved in quantity almost from the first day, the following being the daily quantities in ounces: 31, 31, 21, 32, 49, 53, 38, 58, 52, 66, 62, 82, 94, 65, 74. The albumin decreased to 0.15 per cent.

April 26, 1903. Mr. B. now reports that his general health is good and sends the following report of his urine: Twenty-four hours, ℥lxxxv; color, light amber; reaction, acid; specific gravity, 1015; albumin, 0.05 per cent. (by centrifuge); leucocytes, a few red cells, small, as if from the kidney. Renal cells, some fatty and a few fine and medium casts.

Pathology.—Microscope shows parenchymatous nephritis with hyaline degeneration.

FLOATING KIDNEY. DECAPSULATION AND FIXATION.

CASE 14.—*History.*—Miss B., Newport, Wis., aged 24, nurse. Complains of (1) severe pain in gall bladder, but no colic; (2) jaundice, which is sometimes marked; (3) pain in back, which radiates down the right iliac fossa and legs: (4) drowsiness; (5) puffiness of eyes and swelling of wrists and hands; (6) temperature, 99 to 101; (7) loss of weight; lassitude.

Urine normal. Has a soft, compressible tumor continuous with the liver, and another movable and firm, which can be replaced to kidney fossa. Patient had a severe attack of pain radiating down the right leg in September, 1900, and a second in March, 1901.

In August, 1902, pains returned in right side, and shortly after this she noticed jaundice for the first time. A second attack compelled her to stop work, and after a short time she returned for operation.

Operation.—Oct. 4, 1902. The gall bladder was drained. The kidney was decapsulated and punctured freely several times and drained; then sutured in place. Kidney drained for two weeks and closed. Patient made a good recovery.

Pathology.—Microscopic examination reveals, practically, a normal kidney; the slight cloudiness and congestion being due to the chloroform and manipulations.

Present condition: Free from symptoms. Urine normal. Has some pelvic pain at and following menstruation.

BRIGHT'S DISEASE AND PELVIC DISEASE. DECAPSULATION OF ONE KIDNEY AND LAPAROTOMY.

CASE 15.—*History.*—Mrs. J. C. W., Chicago, aged 41, housewife. Complains of (1) backache; (2) pain in left side in lumbar region, extending up into shoulder and down into leg; (3) burning pain in feet, with swelling; (4) pain in pelvis; (5) dysmenorrhea; (6) headache, nervousness, sleeplessness; (7) frequent micturition; (8) nausea and at times vomiting; (9) constipation; (10) belching of gas after meals, but has good appetite.

Symptoms began eight years ago with nervous prostration. Following recovery she had a pelvic abscess, which was drained. Had excellent health until about two years ago, when she was treated for uterine troubles. Gives no good history as to when her kidney trouble began, but bladder has given her trouble for four or five years. Her kidney is easily palpable in abdomen, and replaceable to kidney fossa. She has some uterine displacement and strong pelvic adhesions, involving the ovaries and tubes.

Urine: Quantity in twenty-four hours, ℥xxx; specific gravity, 1030. Strongly acid. Hyaline and granular casts. Epithelium, small, round, spindle and pavement. Red blood cells and leucocytes. Bacteria. Cylindroids. Uric acid. Calcium, oxalate and urates in heavy deposit.

Operation.—Dec. 4, 1902. Curettage. Freeing of pelvic adhesions. Removal of both tubes and part of each ovary. Kidney decapsulated, punctured, fixed and drained.

Patient's temperature for a week was from 101 to 102, and during the second week she was wandering mentally, but later became rational and made a good recovery, leaving the hospital on the twenty-ninth day. Kidney tissue changes are both interstitial and parenchymatous.

Present condition: Relief of all symptoms (except the bladder). Gaining rapidly in strength and weight.

RIGHT FLOATING KIDNEY. NEPHRALGIA. DECAPSULATION; NEPHRORRHAPHY; APPENDECTOMY. KIDNEY TISSUE NORMAL.

CASE 16.—*History.*—Miss H., Bradford, Ill., aged 24. (Dr. Hawkins.) 1. Burning pain in right kidney, with exacerbations. Pain radiating down in region of appendix, which region was also troubling her. 2. Pain over whole right side of abdomen and down the right thigh. 3. Inability to work. 4. Loss of strength and confined to the house. 5. Attacks of pain in lumbar region, which would disable her for a week at a time, with frequent and painful urination.

Patient has been complaining about three years with symptoms referable to this kidney, and the pain in the region of the appendix was grafted on it in the last two months. Right kidney floating, enlarged and tender. Kidney could be pushed down into the iliac region. There was also tenderness over the appendix.

Urine: ℥xl, pale and clear. Specific gravity, 1007; neutral. Urea, .2 per cent. No albumin and no casts.

Operation.—Feb. 25, 1903. (1) Curettement and packing of uterus. (2) Appendix removed through kidney incision. (3) Kidney drawn up; decapsulated; capsule sutured to wall and incision closed.

Patient did well for three days following operation, when she had a slight rise in temperature to 99.6, and in pulse to 100, with pain in region of right ovary and tube, which spread over the whole abdomen. There was nausea and slight vomiting. Blood examination: 57,800 leucocytes, mostly polymorphonuclear form.

On the fifth day incision opened and gauze drainage inserted. There was no exudate, and there were no signs of infection.

Patient continued with signs of peritonitis, and died on March 9, just twelve days after operation.

Autopsy.—Peritoneal cavity had considerable fibrinous exudate. Kidney and wound normal. Cultures sterile. Appendix stump normal. Right tube slightly inflamed. Left tube and its region congested and inflamed. Cultures showed streptococcus. Descending colon as high as splenic flexure, and the sigmoid congested and inflamed, with fibrinous exudate. Cultures showed streptococcus infection. Death caused by streptococcus infection, probably an old infection of the left tube lighted up by the curettement, or by an infection following the curettement, which is doubtful.

CASE 17.—*History.*—Mrs. H., Chicago, aged 48. (Dr. Peacock.) In Chicago Hospital. Dr. Ferguson, consultant in operating room. Patient complains of (1) pain in the back, radiating down the right side and right thigh; (2) no urinary control; up several times at night and during the day; (3) pain in right iliac fossa.

Previous history: Ten years ago patient had ovaries removed. The commencement of pain is very indefinite, but it became quite severe during the last year.

The kidney is freely movable and very tender. Urine: Specific gravity, 1020; acid; urea, 1.5; hyaline and granular casts; small round epithelium. Considerable blood.

Operation.—March 20, 1903. Appendectomy by Dr. Peacock. Kidney decapsulated and punctured. Sutured in position. Gauze drainage inserted down to kidney. Incision closed. Patient made good recovery, leaving the hospital on the nineteenth day.

Present condition: Patient up and around the house. Relieved of all symptoms. Does not have to get up during the night, and urinates about every four hours during the day.

OBSERVATIONS.

For a synopsis of the histories of the foregoing cases I am indebted to my first assistant, Dr. Hugh Neil MacKechnie, and my associate, Dr. E. M. Brown. It will be observed that my personal experience dates back to 1889. In 1896 a nephritis in a floating kidney was deliberately treated by decapsulation, but not until Jan. 4, 1899, did I begin to remove sections of the diseased kidneys under treatment, and study them under the microscope. While the reports given above are incomplete, from lack of space, still it will be seen that our treatment was justified by the results. In the vast majority of my cases the kidneys were movable and also chronically inflamed. In only two cases was decapsulation carried out for parenchymatous nephritis. The results so far have been excellent and astonishingly prompt. The symptoms of the cases, regarding urinary changes, digestive disturbance, nervous phenomena, skin signs, circulatory and respiratory changes were recognized as not of the severest types of nephritis.

I did not operate on cases with urine extremely scant, very marked hypertrophy of the left ventricle of the heart, edema of the glottis and lungs, Cheyne-Stokes breathing, marked general anasarca, etc., etc. The urinary changes can not be absolutely depended on to indicate the tissue changes taking place in the kidneys until at least a late stage has arrived. It was noticed that a tender kidney is often relieved after its fellow has been decapsulated.

PATHOLOGY.

The pathology, macroscopically observed and handled on the operating table, and a study of the microscopic condition of the organ in a living patient are of superlative interest and importance. An enlarged kidney may have few or no histologic changes, while one normal in size is often surprisingly diseased. A contracted kidney is usually very much destroyed. The intimate relationship between the capsule and cortex of the kidney by adhesions does not give us an accurate idea of the extent of the inflammation. Neither does the appearance of the fatty capsule. The only scientific procedure to pursue to obtain anything like an accurate knowledge of the *status presens* of a kidney under operation is to remove a V-shaped piece of the cortical and pyramidal tissues and study it microscopically.

MICROSCOPIC OBSERVATIONS.

In ten of the seventeen cases a portion of kidney was examined and studied. There were no pronounced changes in three. The pain and tenderness in these three cases of floating kidney must have been caused by something else than inflammation. In five instances the interstitial form of the disease was demonstrated by the microscope, which in these verified the clinical or provisional diagnosis. The microphotographs prepared by Professor Zeit reveal a picture of chronic interstitial nephritis. The proliferation and hyperplasia of connective tissue and areas entirely connective tissue, with obliterated or waxy glomeruli. One also sees islands of partially changed kidney tissue, with atrophic tubules, and tubules with desquamated epithelium; flattened epithelial lining in tubules of diminished caliber and some swelling in the lining of the epithelial cells. The hyaline casts in the tubules are worthy of notice, as are also the thickened capsules of glomeruli and the concentric layers of connective tissue with many nuclei, etc.

OPERATION.

(*A*) *Superficial Oblique Incision.*—Make the skin incision a finger's breadth below the twelfth rib and parallel to it. Cut down to muscular tissue; then dissect the skin and fat from the muscles downwards to the crest of the ilium.

(*B*) *Deep Vertical Incision.*—Go through the rest of the structures as if to remove the kidney through the lumbar route, along the outer border of the quadratus lumborum. In cutting the lumbar fascia, keep well backwards.

(*C*) *Fat.*—On exposing the fat do not tear and traumatize it, as is so often done, but carefully cut with the knife its thin fibrous covering. Do not insert the hand to pull at the fat, but seize hold of it with many pressure forceps and deliver it externally. It will now be found that the kidney is immediately beneath your fingers in the wound.

(*D*) *Delivering the Kidney.*—Do not use the hand to deliver the kidney. Firm pressure on the abdomen and traction made on eight or ten forceps applied to the fat, close to the kidney, will easily bring a movable kidney outside the wound. In some few instances the renal vessels are too short to allow the kidney to be delivered at all. Indeed, it is not necessary to have the kidney dragged out in order to decapsulate it, but if it comes out easily, I do it. When the kidney is situated rather high, and the traction on the forceps does not promptly bring it down, I find a long narrow retractor, with a slight concavity outwards, passed beyond the upper pole, greatly facilitates its delivery.

Splitting and Peeling the Capsule Off.—Incise the capsule longitudinally over the vertex of the kidney for about two-thirds its length, peel it from the cortex with the handle of the knife or finger until it is entirely separated, then slip one end of the kidney through the slit in the capsule, and then the other, and it will be seen that it forms a collar around the hilum of the kidney. If the kidney is movable, I utilize the capsule to suture it in place, and the organ is left in contact with raw muscular tissue which is more vascular than the

fatty capsule and is, therefore, a more suitable structure to form vascular adhesions with the denuded organ.

Disposal of the Perirenal Fat.—Do not remove it or tear it to pieces, but gently displace it to the lower end of the kidney. It is but poorly supplied with blood vessels, therefore as little of the surface of the kidney as possible is left in contact with it, but when placed it furnishes an additional support to the organ.

Puncturing the Kidney.—In most of my cases I have freely punctured the cortex of the kidney in many places. This not only furnishes free drainage for inflammatory products, but also insures a thorough determination of blood to the parts, which hastens resolution and favors repair. It must also be remembered that the fibrous tissue formed for the purpose of repair in the absence of pyogenic organisms has a tendency later on to clear away rather than increase in bulk, and subsequently contract and become cicatricial. Of this we see many instances in surgery.

Drainage.—Drainage should always be established for five to eight days after decorticating the kidney. My experience leads me to use plain gauze and a small rubber tube for this purpose. It is astonishing the quantity of blood serum and urine that saturates the dressing for a couple of days. When drainage ceases remove the tube, and afterwards withdraw the gauze as it becomes loose.

Closing the Wound.—Use small-sized catgut to coapt the muscles and silkworm gut for the skin, the drainage tube and gauze emerging from the outer angle of the wound. After applying the dressing, place a firm pad of gauze or cotton on the abdomen below the ribs whenever nephrorrhaphy has been necessary.

HOW IS A CURE EFFECTED?

This has not yet been fully worked out. It is my opinion that the excellent immediate results are due to the relief of kidney tension and that the permanent benefit accrues in the cases demanding it from the establishment of collateral circulation with the diseased cortex. There are many instances of the formation of vascular adhesions in different parts of the body to support this latter fact.

EXPERIMENTS.

Before experiments on animals can throw any light on this subject we must first produce nephritis in them. In the production of this all efforts have been unsuccessful. I notice in the *Annals of Surgery,* April, 1903, Dr. H. A. Johnson writes on "Results of Decapsulation of the Kidney," being work done on dogs. He operated on 15 dogs; 5 died in from three hours to three days after the operation. The animals surviving the operation were killed. "Changes were studied two, four and eight days; two, three and four weeks; two and two and one-half months." The chief observation in his article is the eighth, viz., "In no case was there any considerable anastomosis between the renal and perirenal blood channels." It must be observed that in these experiments the kidneys of the dogs were normal and did not require additional blood channels for physiologic purposes, and also the organs were returned within the fatty capsule, which is but sparsely supplied with blood vessels.

In conclusion, I have no hesitation in affirming that decapsulation of the kidney in acute, subacute and chronic nephritis, both interstitial and parenchymatous, is a practical and effectual surgical procedure. Its limitations are not yet determined. While it can be pointed out that regeneration of kidney tissue is possible, it is folly to claim this procedure to be a panacea for Bright's disease.

10 Drexel Square.

DISCUSSION

ON PAPERS OF DRS. WHITACRE, GUTHRIE AND FERGUSON.*

DR. ARTHUR DEAN BEVAN, Chicago—The treatment of suppression of the urine is a subject to which my attention has recently been called by a number of cases, and one which I do not believe has been very well worked up by the profession. Recently I presented to the Chicago Surgical Society a case of anuria treated by surgical interference, and I found that the great majority of the members had not dealt in this manner with any case of anuria. This was my first case, the subject was rather new to me, and it gave me an opportunity to investigate it with some care. I came to the conclusion that the method had not been sufficiently emphasized and felt that the disease should be treated as a surgical entity. I attempted to make a clinical classification which would enable us at the bedside to determine on what line we should work in order to aid the patient. The classification which I decided on was as follows: 1, Obstructive anuria; 2, reflex anuria; 3, nephritic anuria.

The reflex condition, of course, is the one which is the most common and which gives the best prospects for relief under surgical interference. The reflex anuria, I came to the conclusion from the study of the cases, was a rather rare condition, although from the work of Getzel, the assistant of Israel, there can be but little doubt that such a condition does exist. Getzel's experiments, by increasing the renal tension, show that it would decrease the quantity of urine, in either or both kidneys, according to the application of the pressure, and when the tension was increased to a certain point in both kidneys, there would be entire suppression of the urine. Of course, in case of hydronephrosis on one side, fixture of the hydronephritic sac has been followed by relief of the anuria. The case presented by Dr. Whitacre, I think, comes under the nephritic group. Since reading this paper before the Chicago Surgical Society I have had an opportunity of doing a nephrectomy under nitrous oxid gas. The operation can be done in from five to eight minutes, during which time you can easily keep up the anesthesia, and this kind of anesthetic is especially valuable, as we are never sure of diagnosis until we make an exploratory operation. It may be a case of nephritic anuria; it may be a case of the obstructive variety, or there may be a stone in the kidney. A nephrectomy gives an opportunity of exploring the pelvis and relieving any abnormal condition which may be a cause of the anuria. I should throw out of consideration the decapsulation of the kidney for anuria and would say that the operation of choice was a nephrectomy under an anesthetic which could do no danger to the kidney tissue, such as nitrous oxid gas or infiltration anesthesia.

DR. WM. JEPSON, Sioux City, Iowa—It is hard for us to say, with our present knowledge, of just what value decapsulation of the kidney may be. One of the papers deals with the topic of who was the originator of the treatment by decapsulation; I know that Edebohls was not the originator, because we know that Redner did this operation in 1892 at the suggestion of Professor White, and he reported a number of cases before the British Surgical Association in 1898, in which he had this topic under consideration. In 1899 Israel reported 19 cases. So that I think we are safe in stating that Dr. Edebohls was not the originator of this method. Harrison reported 6 of these operations in 1896, and called attention to this method of stripping off the capsule in order to relieve the tension, and then, in addition, there were the cases of Professor Israel. Babinsky carried out these observations, and his work was proven by the fact that he removed sections of the kidney in order to determine just what the lesion was. Therefore, in cases of chronic nephritis we can hope for very little benefit from stripping of the capsule, but it is in those cases where we have an interstitial nephritis with an involvement of the surrounding

* The paper of Dr. Whitacre appeared in THE JOURNAL, May 23, 1903.

structure and thickening of the capsule, and especially where we have a hemorrhage under the capsule, that this method will do the greatest amount of good. On the other hand, you will remember that Edebohls concedes the idea that by separating the capsule from the kidney it produces a restitution in the normal functions, even to the extent that the whole tubules have radically become regenerated. Now, with such opposing views, should we not be very careful and considerate as to whether these operations do or do not do the kidneys good? I am sure that we have all observed that marked benefit would follow an operation which was primarily undertaken as an exploratory operation. I think probably splitting of the capsule or of the kidney produces this change.

DR. ARCHIBALD MCLAREN, St. Paul, Minn.—I wish to emphasize the point made by both Drs. Bevan and Jepson, namely, that the advantage which we sometimes get in these cases of painful and uncomfortable kidneys, is often due to the splitting of the capsule, without the decapsulation. There are not many of us who are ready to recommend stripping the capsule in chronic nephritis as yet. We may later come to believe that this is the proper procedure. I can remember a number of cases where the conditions found were inexplicable with the results produced by merely splitting of the capsule, such as relief from the pain, disappearance of the albumin, etc., and many of these cases got considerable permanent relief. I have seen a few cases that have been decapsulated; although they received some immediate benefit, this improvment did not last long.

DR. RICHARD H. GIBBONS, Scranton, Pa.—The first man in all the world to recommend surgical interference for the cure of Bright's disease was Edebohls. All the others who did the operation did it incidentally, just as Dr. Ferguson did. They did not do the operation for the relief of Bright's disease; they did the operation for tension or some other cause which they supposed existed, but which they did not find when they operated. It was for this same reason that Israel did the exploratory operation and split the capsule, but Edebohls not only split the capsule, but he entirely decorticated the kidney; not only one kidney, but both kidneys, and afterward found that the condition could be relieved by surgery, and there is no man to whom credit for this work more justly belongs than to Edebohls, as he came out and recommended it for the condition, and would have had to have accepted his share of the damnation had it proved a failure. I believe so much in this method of splitting the capsule and detaching it in chronic Bright's disease as to have done the operation on my own sister, and at the same time I took out her appendix. I have had a number of cases of Bright's disease recover by this treatment, and many of them have been cases which have been proved to be this disease by the subsequent examinations of one of the best pathologists in Philadelphia. I had a case recently where I detached the capsule, and in which there was a number of multiple cysts in both kidneys, and the patient got well. Only four weeks ago to-day I operated on a young lady with a retroverted uterus, loose appendix and diseased kidney on the right side. She had all the symptoms of appendicitis, the diagnosis having been confirmed by Dr. Brooks of the Post-Graduate Hospital, New York. I referred her to Edebohls, as I hesitated to advise an operation without her seeing him. He recommended operation with fixation and decortication, which was almost entirely what I had recommended. She left the hospital last Sunday; her symptoms were improved in every way and the albumin in the urine very much diminished. Another case in relation to Dr. Whitacre's paper was a young woman on whom six weeks before I had operated for appendicitis, and expected to fasten a loose right kidney. I found a number of abdominal adhesions and decided to take out the appendix anteriorly. She got no relief and showed the usual symptoms of appendicitis and loose kidney. I operated on her several months afterward and fixed the right kidney, but did not touch the left kidney. She had all the symptoms of chronic Bright's disease, as proven by Dr. Brooks' examination. She immediately went into a state of surgical anuria. She died the latter part of the sixth day from complete suppression of urine, having passed six ounces up to that time. If I had only opened that woman on the left side, exposed her left kidney and decorticated it, the probabilities are that she would not have died from that condition.

DR. RAMON GUITERAS, New York—I think that the operation for chronic Bright's disease is still in its infancy, and it behooves us all to work with the object of improving our technic and bringing this operation to a position where it will be generally accepted by the profession.

Last year I read a paper before the American Genito-Urinary Association at Atlantic City, which was a preliminary report on this subject, and next week I am about to present a similar paper before the Congress of American Physicians and Surgeons in Washington. As there are so many varying opinions as to the advisability of attempting such an operative procedure, I have written to 150 of the most prominent surgeons in this country, and have mailed them circular letters covering the most important points connected with the operation, and have been very much pleased to find how many of them have responded to my letters. The opinions of these gentlemen, however, vary much. Some condemn it as an operation having no surgical or pathologic *raison d'etre*, while others reply at length, describing their experiences in a most enthusiastic manner.

Of course, as you know, the object of decapsulation of the kidney in this operation is to increase its circulation. Some of the leading medical men have likened the kidney after this procedure to the lung where there is a double circulation, the bronchial fortifying the pulmonary system. Dr. Johnson of San Francisco, in order to test the truth of this assertion, operated on a number of dogs in which he decapsulated the kidney for the purpose of investigation. He states that the blood supply is but slightly increased, if any, and a new capsule forms which in time becomes thicker and denser than that of the original one. It would take too much time to consider the question of Bright's disease, but as you know it is a disease of the kidney where either the connective tissue, the blood vessels, the Malpighian tufts or the tubules must be involved. Bad cases of Bright's disease very often show very little in the urine, while cases of transient albuminuria and cylinduria are often seen where no pathologic changes have occurred in the organ, although such changes will occur. if the cause of the transient trouble is not corrected. These latter cases, we believe, are benefited or permanently cured by the operation mentioned.

Considerable has been said of late concerning unilateral Bright's disease, and some have spoken of this disease as present at times in only one kidney, or its being more marked in one kidney than in the other. It is a very difficult thing, it appears to me, on exposing the kidneys to say this kidney has nephritis and the other one has not, or this has nephritis to a greater or less extent than the other. Such fine discernment from a gross pathologic standpoint from viewing the outside of the organ when the capsule has been stripped off is, to my mind, next to impossible. In order to investigate the subject of unilateral nephritis I had the autopsy records of 500 cases of deaths from chronic Bright's disease looked over, and in only one case did I find the record of a purely unilateral affection, and this one, to my mind, could not be relied on. In only 14 cases out of the 500 did the records show that one kidney was more involved than the other. In nearly every case a very careful pathologic examination was made after removal of the organ.

DR. L. L. MCARTHUR, Chicago—Last year I undertook the relief of a chronic interstitial nephritis in the case of a young woman referred to me by members of this Society, Dr. Favill of Chicago and Dr. Norman Bridge of Los Angeles, who for six months had had the patient under treatment, and finding her but slightly benefited by medical assistance, treatment, change of climate, etc., had recommended removal of the capsules of her kidneys and requested me to do it.

I had little confidence in any good that might arise from the operation, but agreed to it because of the reports contained in the literature. Before the operation, I took pains, in addition to the examinations which they had made, to make a sep-

arate collection of the urines from both kidneys at three successive times for three successive weeks. The urine, when microscopically and chemically examined, showed the presence of Bright's disease equally affecting both kidneys. I then said that I would decorticate one kidney to see whether that kidney would be benefited as compared with the other. I did so. The quantity and quality of the urine from the operated kidney was very much increased and improved as compared with the other kidney. The patient improved physically; in fact, she was so much better that in the course of about three months she came back and urged the decortication of the capsule of the other kidney. Her condition physically was better; the edema of the eyelids had disappeared and the face assumed a more normal color.

I removed the capsule of the opposite kidney and its urine soon assumed as good a condition as that from the other kidney. Segregation was made in order to determine whether there was improvement or not.

There is surely some value in this operation, although just what the value of it may eventually be remains for time to tell. I do not think it is going to be good for every case of chronic or acute Bright's disease; we must yet learn to pick out the cases which will be benefited, and I would like to say further, in regard to Dr. Whitacre's case, that I think it is a mistake to cut away the capsule, since by a little procedure the capsule can be preserved and will make a good platform for the fixation of the kidney. This consists in making a transverse equatorial incision on the posterior aspect of the kidney, loosening the capsule first of one-half then of the other; when loosened the poles of the kidney can be delivered, leaving the empty capsule in one piece in front of the kidney. This can then be used to suture to those structures to which the movable kidney is usually fixed by a nephropexy. A detailed report of this case will be published later.

DR. F. A. DUNSMOOR, Minneapolis—One thing has not been said here to-day in the papers read. Experiments were made ten years ago by Dr. Wyman of Detroit, to demonstrate the production of Bright's disease in dogs by temporary ligation of renal vessels associated with stripping of the capsule, half of the method now used for a cure. In regard to the case of anuria, I agree with Dr. Bevan that many of the cases of post-operative anuria are due to the anesthetic, as the operations were made with perfectly aseptic methods and, therefore, it would seem that this could be the only cause for the anuria. I also wish to agree with him and with the last speaker that it is not necessary to strip the capsule completely, since the incision relieves the tension.

DR. RANDOLPH WINSLOW, Baltimore—I wish to mention a case under my care, which is somewhat different from those that have been mentioned, but which, nevertheless, is in the same line. A young woman who had been confined in the central portion of North Carolina, was evidently in a thoroughly septic condition in consequence of that procedure. After many weeks, her condition having become so bad that her life was despaired of, she was sent to Baltimore. She came practically on a litter, and it was feared she would die before she could get into the hospital. She did not improve on medical treatment; there was pain over the right kidney and pus in her urine with a septic temperature chart. She was subjected to a cystoscopic examination, without determining anything in particular and, owing to the fact that she had pain over the right kidney, it was thought that there was some trouble with that organ. The kidney was exposed and apparently there was no abscess connected with it. I presume there was some pyelitis. There was nothing which, in my opinion at the time, justified either removal of the organ or nephrotomy. I punctured the kidney in a number of places and then stripped the capsule from it. The patient improved rapidly. The pus disappeared from the urine and in a very short time she was sufficiently well to go home, and continued well when last heard from.

DR. H. J. WHITACRE, Cincinnati—In reference to the classification suggested by Dr. Bevan: First, I did not have the pleasure of reading this valuable article until mine had been completed, and, second, had I read the article I would not have followed the classification. My experience in this condition leads me to believe that this classification is incorrect. Dr. Bevan has given his classification into the obstructive, the reflex and the nephritic forms. One object of my paper was to present serious objections to the inclusion of obstructive lesions under the heading of suppression of urine. I do not believe that this form belongs under the heading of suppression of urine at all, no more, indeed, than does retention of urine.

I wish to likewise make objection to his second and third forms. True suppression of urine always concerns the parenchyma of the kidney, therefore all forms must be nephritic and a reflex suppression must likewise be a nephritic form. The classification which I have presented includes these two forms and more too. In all cases of true suppression of urine the parenchyma of the kidney is at fault. This may be a reflex fault, a degenerative lesion, the result of lessened heart action, the result of an anesthetic, or the direct result of trauma. Objection has been made in the discussion to the operative treatment of suppression of urine as irrational and improper. It was impossible for me to read my entire paper. It will be found, however, in the complete paper that such is by no means advised for all forms of suppression of urine. It is by no means advised that a degenerative lesion be submitted to operation, but that every possible agent be employed to improve the nutrition of the degenerated cells and to improve the flow of good blood to them. Nobody would think of treating a suppression of urine which occurs in shock from lowered blood pressure by administering an additional shock. Suppression from trauma could not be improved by adding another trauma. It is the purpose of the paper to classify the etiologic factors present and to show that operative treatment by decapsulation is not only rational, but actually demanded in those cases of suppression of urine that result from a reflex circulatory or vasomotor disturbance in the kidney. My reasons for recommending this treatment have already been given in that section of my paper which deals with the pathology.

Dr. Bevan has recommended nephrotomy as a more rational operation. It seems to me that a nephrotomy would not meet the indications, unless it split the kidney from end to end. The tension is exerting its deleterious influence on every cubic mm. of kidney parenchyma, and a single short incision would relieve the tension over only a very limited area. I do not see the advantage of opening the pelvis of the kidney. it is not at fault at all. I should most unhesitatingly recommend such procedure when there is reason to suspect a calculus in the pelvis.

Dr. McArthur has recommended that only an equatorial segment of capsule be removed, or, if the entire capsule has been stripped off, that this be turned back under the kidney and used to anchor it. I think that I caused a kink in the ureter of a floating kidney by doing this very thing.

I have done decapsulation for Bright's disease once on the large white type of kidney. The results were not satisfactory, however, and I felt at the time of the operation that the operative procedure was in reality not relieving his kidney very much. I do not believe that this type of kidney will yield good results by this method.

DR. ALEX. H. FERGUSON, Chicago—I think there are one or two points in regard to the operation that ought to be made a little clearer. When the kidney is exposed the fat ought not to be taken away, but left displaced below it. The sudden effect which this operation has on the urine and the symptoms of the disease is simply marvelous. They are usually better even the next day, and the old pain is gone, and the albuminuria and the casts decrease within a couple of weeks. But how is this effected? That is the question that concerns us. First probably by relief of the tension. That would pertain to those cases in which there was intracapsular tension, such as would be produced by acute inflammation, like those cases of Reginald Harrison. In all the acute and subacute cases there is pain and tension, but later comes a stage where there is no

tension, but just the reverse, a contracted kidney. There are various stages of contracted kidney that are more or less benefited by decapsulation. How does this come about? By collateral circulation, I think. Now experiments have been performed on dogs by Johnson of San Francisco, and in no case, he states, was there any considerable anastomosis established between the renal and perirenal blood channels. He returned the kidney back into the fatty capsule, where there would not be much attachment of a vascular nature seen. Experiments on dogs with normal kidneys do not bring the results that operations on a person who is suffering from nephritis do. I had a patient who came to me suffering from an infection of the kidney. I opened the kidney and the wound closed rather too soon, and the patient went home; the pain returned and she came back. I then opened the kidney again and removed a portion of the organ. There was a vascular connection formed between the kidney and the pseudocapsule.

In regard to this claim to priority, I do not wish to be misunderstood. But when a certain man does certain work and publishes it, not in an obscure medical journal, but in THE JOURNAL of the American Medical Association, on a certain date, and another man does certain work along the same line and publishes the result of his labors one month and eleven days afterward, it would seem that the first author should be the one entitled to first credit. But that does not matter very much.

EVOLUTION OF THE MAMMALIAN STRAIGHT GUT.

WITH SPECIAL REFERENCE TO PERITONEAL CHANGES INCIDENT TO ROTATION.*

W. T. ECKLEY, M.D.
CHICAGO.

As is generally conceded, the adult peritoneum of man, while a macroscopic structure of liberal proportions, is, nevertheless, complex beyond the ken of the ordinary student, without embryologic study. To such an extent have certain organs as spleen, liver, stomach, pancreas and colon migrated from their primitive location in the posterior mid-line of the body cavity, and contracted such intimate and deceptive physiologic adhesions, that even embryologic speculation as to the *rationale* of their migration was slow of general acceptance by the profession. If, now, to these numerous physiologic departures there be superadded pathologic departures incident to inflammatory processes, some conception of the difficulty confronting the student in his dissecting-room study may be imagined.

Within recent years our standard text-books on anatomy were monumental in their respective chapters on the peritoneum, to the most flagrant violation of perspicuity. There is no longer doubt that in the study of the abdominal organs and their investing peritoneum, two methods must be pursued: 1. The practical method by which each organ, with its corresponding peritoneal investment, is to be identified and studied *in situ*. 2. The embryologic method, by which the products of the primitive straight gut, Wolffian bodies, Müllerian ducts, and indifferent sexual gland are studied, in their successive developmental stages, from the simple to the complex. According to Huntington, the peritoneum of certain lower animals should be studied along with the human peritoneum, because in them the permanent adult arrangement corresponds to one of the early embryonal human stages. Huntington says:

It is doubtful if the detailed developmental stages in man can ever be clearly comprehended unless the student will for himself examine the conditions, and perform the manipulations (of rotation) in one of the lower animals. The necessity of keeping the three dimensions of space in mind, and the fact that certain structures during and after rotation cover and obscure each other, make diagrams and drawings unsatisfactory unless the actual examination of the object itself is combined with their study. The cat answers every purpose of this study admirably.

It is believed that the mechanical device here presented will be of some advantage to the teacher in presenting the difficult subject of the anatomy of the peritoneum to large classes of students. It has the further advantage, by virtue of its strength and stability, of being available for the use of students, who can readily learn its proper manipulation. The device, constructed principally of rubber dam and inflatable bags and tubes, simply reflects the embryologic illustrations in our text-books. It is not intended to supplant the practical study of the peritoneum of man or the lower animals. We believe it shows with tolerable accuracy the mechanical principles involved in the following points:

1. The primitive straight gut attached (a) to the posterior abdominal wall by a dorsal mesentery; (b) to the anterior wall as low as the umbilicus by a ventral mesentery; (c) to the umbilical region by the intra-embryonal part of the yolk stalk.

2. A dilation of the gut tube, differentiating the primitive tube into stomach and intestine, and its investing peritoneum into mesogaster (ventral and dorsal) and mesentery.

3. A drawing out of an U-loop of gut from the dorsal wall, increasing the length of the mesentery, and presenting an upper and a lower limb separated at the neck of the loop by the superior mesenteric vessels.

4. Evagination of liver and gall ducts from the ventral wall of the duodenum into the anterior mesogaster, showing location of the primitive gastrohepatic omentum and the derivation of the hepatic peritoneum from the anterior mesogaster.

5. Evagination of pancreas and its duct from the dorsal wall of the duodenum into the posterior mesogaster, showing the primitive peritoneal investment of this organ.

6. Location of the spleen in the posterior mesogaster, in close proximity to the pancreas, showing the gastrosplenic omentum and the phrenicosplenic ligament derived from the posterior mesogaster.

7. The broad ligament of the liver, the hepatic peritoneum, the gastrohepatic or lesser omentum, the gastric peritoneum, the mesoduodenum, the splenic and pancreatic mesenteries, and the gastrosplenic omentum—all of which are derived from, and are specialized parts of the primitive mesogaster.

8. Rotation of the mesogaster whereby liver, stomach and spleen begin to assume their adult relations, and dimly foreshadow the beginning of the lesser cavity of the peritoneum.

9. Evagination of posterior mesogaster to the left, showing the formation of (a) the greater omentum; (b) the foramen of Winslow; (c) implantation of the posterior mesogaster and pancreas on posterior abdominal wall, to the left of the mid-line of the body.

10. Rotation of the U-loop of the intestine from left to right about the long axis of the superior mesenteric vessels, showing the transverse duodenum passing beneath these vessels, and taking up its adult position.

11. Differentiation of the gut caudad to the attachment of the yolk-stalk into a large and small intestine.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

The following summary, founded largely on Heissler, includes the salient points in the evolution of the alimentary canal and its accessory organs, and points out (a) the condition of the structures during the period of primary parietal peritoneum before rotation; (b) the migration of organs, consequent on rotation, when they acquired their adult position and relations; (c) the structural changes in certain localities, in both visceral and parietal peritoneum, incident to adhesion between peritoneal surfaces; (d) the mechanism of rotation, whereby liver, stomach, spleen, pancreas, duodenum and intestines departed to greater or less degree from their primitive location in the mid-posterior line of the abdomen. I also append observation on 200 cadavers with reference to rotation.

1. The abdominal part of the alimentary canal, in the second week of embryonal life, consisted of a gut tract separated in part only from the yolk-sac.

2. In the third week, the gut tract assumes somewhat the form of a straight tube, presenting, near the head-end, caudad to the future stomach, the beginning of an evagination, the future liver.

3. In the fourth week the straight gut dilates cephalad, initiating the future stomach. The lumen of the bile passages is completed, and the liver-diverticulum divides, thus foreshadowing the future major lobes of the liver; the pancreas is evaginated from the duodenum, growing subsequently into the mesoduodenum and posterior mesogastrium.

4. The original straight gut in the fifth week becomes somewhat convoluted, and foreshadows the first tangible evidence of its future complexity in the U-loop, and a disposition to differentiate into large and small intestine. The loop consists of (a) an apex attached by the vitelline duct to the yolk-sac; (b) of a descending limb, which subsequently develops the major part of the small intestine caudad the duodenum; (c) of an ascending limb from which the future cecum, ascending and transverse cola, and distal end of the ileum are derived. The loop, by traction exerted through the yolk-sac, now projects its developing coils (up to the tenth week) through the open abdominal walls into the hollow of the umbilical cord, thus forming, according to Huntington, the so-called umbilical embryonal intestinal hernia. It should be noted that growth proceeds from the apex of the loop; that growth of the descending limb of the loop is rapid, while that of the ascending limb is slow.

5. In the sixth week the duodenum, enclosed in the mesoduodenum, and presenting its well-advanced hepatic and pancreatic evaginations, is fully differentiated from the stomach, and develops its primary duodenal loop. At this period the cecum is formed by buddation and the rectum is developing.

6. In the seventh week the transverse and descending cola are indicated, and, by a process of unequal growth, the cephalic end of the colon differentiates into cecum proper and appendix vermiformis.

7. In the eighth week the gall bladder is formed, and the anlage of the spleen is first observed.

8. In the tenth week the loop of small intestine, which up to this time was encouraged to protrude into the hollow of the umbilical cord, begins to enter the abdominal cavity, a circumstance due to the closing in of the somatopleure on the future umbilical opening.

9. In the twelfth week the histologic characters of the adult peritoneum become established and rotation occurs, a process by which organs, thus far in the mid-line of the body cavity, begin to assume their adult relations.

At this period, the third month of fetal life, immediately preceding rotation, the parts of the alimentary canal with their investing peritoneum and blood vessels, are about as represented in the model. It may be in order now to review the salient features presented before rotation, in order that the post-rotatory locations and relations of organs, with consequent loss of peritoneum in certain places, may be better appreciated.

The stomach appears in the mid-line as a dilatation of the initial end of the intestine between two layers of peritoneum known as mesogastrium. As the stomach enlarges it displaces these two layers, and gastric peritoneum is the name given to the displaced membrane.

The double layer of peritoneum, which, enclosing the stomach, proceeds, ventrad to the anterior and dorsad to the posterior abdominal wall, under the name of ventral and dorsal mesogastrium respectively.

The liver, developed as an evagination from the ventral surface of the duodenum, acquires its artery from the gastroduodenal which originally traversed the space of the posterior mesogaster and entered the anterior mesogaster. As the liver grows, it displaces peritoneum (anterior mesogaster) and the displaced membrane is called hepatic peritoneum. The liver is now seen to occupy a place in the mid-line of the body, anterior to the stomach, between two layers of ventral mesogaster.

The two layers of peritoneum bridging the space between the stomach and liver, is a part of the anterior mesogaster called the gastrohepatic (and containing the root structure of the liver) or lesser omentum. Likewise, the two layers of anterior mesogaster extending from the liver to the diaphragm constitute the falciform ligament of the liver.

Pancreas.—The pancreas arises as an evagination from the duodenum. It grows into the mesoduodenum and into the adjacent segment of the posterior mesogaster.

The spleen develops from mesodermic tissue near the cephalic end of the stomach, between two layers of the posterior mesogaster, and subsequently takes up its adult location as a result of rotation.

The mesogaster at this period consists of two layers of peritoneum, enclosing the stomach, liver, spleen and pancreas. Its four parts unoccupied by these organs are the falciform ligament, the lesser omentum, the part attached to the posterior wall of the abdomen, and the great omentum.

The primitive duodenum extends from the stomach to the neck of the U-loop of intestine. It obtains at an early period its nourishment from the primitive gastroduodenal artery, from which the hepatic artery is ultimately derived. It has a well-marked dorsal mesentery, the mesoduodenum, consisting of two peritoneal layers.

The U-loop, from which the small intestine caudad of the duodenum and the future ascending and transverse cola are derived, is between two layers of primitive dorsal mesentery, which finally differentiates into the mesentery proper and the mesocola of the ascending and transverse cola.

It will be observed that at this period, before rotation, the walls are covered by primary parietal peritoneum, and that the alimentary canal, liver, stomach and pancreas are invested by primary visceral peritoneum.

As a sequence of rotation, a transposition of organs occurs by which the liver and spleen appear laterad to the stomach. The stomach itself assumes now a more horizontal position in place of its vertical embryonal position, and consequently retaining distorted relations to liver and spleen, through their respective omenta.

The posterior mesogaster evaginates to the left, forming great omentum, and its cavity the lesser cavity of the peritoneum. As Huntington puts it:

> The changes which are to be observed in the later stages, depend principally on a peculiar feature characteristic of the development of the dorsal mesogastrium. This feature consists in the extreme redundancy of the membrane, which grows out of proportion to the requirements of its visceral connections, and to a certain extent becomes independent of the direct mechanical purpose of carrying blood vessels to the viscera.

The mesoduodenum immediately succeeding the stomach has right and left surfaces which embrace the head of the pancreas. It falls to the right, presenting thereafter ventral and dorsal surfaces with the head of the pancreas resting on the vertebral column, vena cava, and right kidney.

Note the relation of the duodenum, superior mesenteric vessels and colon at the neck of the U-loop. Upon rotation, the duodenum is ventrad, the colon dorsad, with the vessels between. After rotation, the relation of the duodenum and colon are reversed.

Mechanism of Rotation: (a) The large intestine passes ventrad and dextrad across the jejunoileal coils toward the cephalic end of the abdominal cavity, and lies transversely along the greater curvature of the stomach. (b) The cecum turns to the right against the caudal surface of liver and ventrad of duodenum, and reaches the ventral surface of the right kidney. The colon is crowded cephalad; the small intestine to left and downward. The small intestine rotates about the axis of the superior mesenteric vessels, bringing the transverse duodenum beneath these latter, and in contact with the vena cava and aorta.

Peritoneal losses, the result of adhesion, are sustained in the following localities: (a) The ascending and descending cola lose their visceral peritoneum at contact point with the walls, while their respective mesocola become secondary peritoneum for the posterior abdominal walls in these regions. (b) The second stage of the duodenum loses its visceral peritoneum dorsad, where, as a result of rotation, it continges the abdominal wall and right kidney; also where it lies dorsad to the hepatic flexure of the colon. (c) The transverse duodenum suffers peritoneally where it rests beneath the superior mesenteric vessels, and on the vena cava, aorta and vertebral column. (d) The great omentum suffers concrescence of peritoneum at the contact point of the left kidney, pancreas, transverse colon and mesocolon, and on the posterior abdominal wall in the neighborhood of the diaphragm.

The following observations on peritoneum and alimentary canal were made with special reference to developmental sequences of rotation, on 200 bodies, and appear as a dissecting-room record:

1. Non-concrescence of great omentum. In ten instances adhesion between anterior and posterior layers of great omentum had not occurred.

2. Foramen of Winslow obliterated. In twenty-five instances, obliteration of the foramen of Winslow, presumably from inflammatory causes, had taken place. In seven of these twenty-five cases there were evidences of extensive inflammation of the right pleura. This would seem to be a practical illustration of the possibility of a septic fluid in the right pleural cavity gaining access to the peritoneum through the hiatus diaphragmaticus.

3. Meckel's diverticulum. In fourteen instances Meckel's diverticulum was present. The longest was five inches, the shortest one inch in length; the smallest was about the size of an ordinary sewing thread, and patulous.

4. Ascending mesocolon. In twenty-two instances there was a well-defined mesocolon and mesocecum. This was evidently a case in which fusion had failed to occur between the primitive mesocolon and the parietal peritoneum. The mesocolon was traceable to mid-line.

5. In twenty-six cases there was a well-defined descending mesocolon, and undoubtedly instances of a survival of the primitive descending mesocolon.

6. Primitive mesentery. In seven instances the only mesentery proper was a primitive one, attached about the superior mesenteric vessels.

7. Long mesosigmoid. In twenty-five instances the mesosigmoid was unusually long. In one case the omega loop was 28 inches in length.

8. Little fat in great omentum. In forty instances the great omentum contained practically no fat. In four of these forty cases, adhesion had not taken place between the anterior and posterior layers of the great omentum.

9. Mesentery of gall bladder. In four instances the gall bladder had a distinct mesentery; in one case it was 2 inches in length. (Now on display in pathologic exhibit.)

10. Extensive adhesions. In forty-five cases there were extensive peritoneal adhesions, both local and general. Especially extensive in regions of gall bladder and appendix.

11. Non-concrescence. In five instances there was no concrescence between the deep layer of the great omentum and the transverse mesocolon.

12. Loss of mesosigmoid. In twenty-three instances there was complete loss of mesosigmoid.

13. Arrested rotation. In four instances arrested or faulty rotation deposited the large intestine entirely to the left of the median plane of the body.

14. There are two varieties of peritoneal adhesions. (1) Physiologic; (2) pathologic. Histologically the two differ in degree only, and I believe it is generally conceded that the physiologic ones are the weaker.

979 Jackson Boulevard.

DISCUSSION.

DR. LEMOYNE WILLS, Los Angeles—I have been fortunate to teach this branch for the past fourteen or fifteen years, and I know of nothing harder to teach a student than the practical understanding of the peritoneum. I think it is a great pity that Dr. Eckley did not have his apparatus here to-day, and I hope to be able to get one and use it. I do not think the practitioners of medicine who have been practicing fifteen or twenty years know very much about anatomy, and it would be a very good thing if we had more papers like this.

DR. RICHARD H. GIBBONS, Scranton, Pa.—This paper is far more important than a peck-measureful of papers on appendicitis. There is nothing that has given me more courage to go out and do my work than the teachings I got from Dr. Leidy on the peritoneum.

Veratrum Viride in Puerperal Eclampsia.—De Bustamente adds his testimony to that of others in regard to the value of veratrum viride in eclampsia. He reports in the *Revista Med. Cubana* four cases thus treated. The convulsions were definitely arrested in all, but severe vomiting followed in 2. One patient was injected three times on following days, the last time as a prophylactic measure, when premonitory symptoms indicated the return of the convulsions. Her pulse fell from 99 to 60 and 54 each time in an hour afterward. He injected 1 gm. of the fluid extract, but in future will inject half the amount at a half-hour interval, in the hope of obviating the vomiting. The effect on the eclampsia was unmistakable and has convinced him that this drug is superior to all others yet known for this affection.

PITYRIASIS ROSEA.

AN ERYTHEMATOUS ERUPTION OF INTERNAL ORIGIN.*

LUDWIG WEISS, M.D.
Attending Physician to the Skin and Genito-Urinary Service, German Poliklinik; Dermatologist, Hebrew Orphan Asylum.
NEW YORK.

The disease of which I intend to speak to-day does not belong to those very frequently observed. Its frequency, according to statistics, is between 5 and 12 per cent. of all skin affections presenting themselves for treatment. When we consider that the affection, by not causing imminent symptoms, is apt to be overlooked by the patient, its frequency will be somewhat augmented. If we add to this fact that the discernible features of the disease greatly resemble another skin eruption—tinea maculosa and circinata—we have another source of increased frequency, which must be accounted for when estimating the ratio of its occurrence among the dermatoses.

It is strange that even busy dermatologists will at times encounter no case at all, while at other times the well-known mysterious multiplicity of cases will materialize itself by a string of cases within a limited period. Hyde saw 87 cases in 18 months. The spring and fall seasons seemingly enjoy the distinction of producing the disease. Generally speaking, it is a borderline question between herpes tonsurans maculosus and squamosus corporis and pityriasis rosea; the latter, an erythematous eruption of internal origin.

HISTORY.

An affection like pityriasis rosea, with its sudden onset and with its profuse crop of lesions resembling those of an acute exanthema in some respects, could not easily have escaped the attention of dermatologists. It was not unknown to the older authors. In the chaotic condition of dermatology before Hebra, skin affections were described solely by their most discernible signs and effects, regardless of their anatomo-histologic conditions, and labeled with names the purport of which is sometimes hard to grasp. To mention only a few instances: Willan, the pathfinder in dermatology, in 1798, under the name, roseola annulata, mentions an affection which corresponds with the circinate form of the disease in question.

Rayer, in 1828, by the term, erythema annulatum, describes a skin disease which closely resembles pityriasis rosea.

In 1857, Erasmus Wilson,[1] under the name of lichen annulatus serpiginosus, describes a skin affection, "small, flat, erythematous discs, bounded by a sharp and distinct margin . . . . and converted into rings." A description which closely resembles pityriasis rosea.

In 1862, Bazin,[2] in describing the different forms of pityriasis, mentions one variety, pityriasis rubra aigu, depending on internal causes, especially on a "gouty and herpetic diathesis." He terms it pityriasis maculata et circinata. The former answers the description of the maculous form of our pityriasis rosea. Bazin was the first to mention also the annular form, and by so doing describes a hitherto unnoticed form of the disease, believing it to be of idiopathic origin.

Shortly after, in 1868, the affection was recognized by Hardy,[3] and excellently described under the name of pityriasis circiné. He cautions against confounding it with tinea circinata (*l'herpes circiné*), giving valuable differential diagnostic points.

The first to make the affection known as a disease *sui generis* was Gibert,[4] in 1860, one of the many great talents that the "St. Louis" in Paris has produced. His classical description is yet recognized as the standard by which the affection which bears his name is diagnosed. Gibert, however, describes only the macular variety of the disease, which is rather strange and adds somewhat to the confusion existing. As the disease in almost every instance occurs in the maculo-annular form, we must infer that Gibert has seen a peculiar macular form of it, or that there may be two forms of pityriasis rosea.

The disease was practically unknown here and on the continent with the exception of France, where the older authors had described it, as we have seen, rather imperfectly under various designations; when Duhring,[5] in September, 1880, in a paper read before the fourth annual meeting of the American Dermatological Association, independently and without the knowledge of the researches of others, published his six cases, giving an excellent description of the affection. Therefore, he may justly claim the honor of having been the first American to deal with it. In comparing his cases later he found them to correspond with an affection described by Bazin under the name of pityriasis maculata et circinata. Failing to find an account of it in Gibert's work he gives the honor of priority to Bazin. This, however, was an oversight, as in the third edition of Gibert's book, which appeared in 1860, two years before Bazin's, on page 402, Gibert describes the disease which bears his name as pityriasis rosea.

The views on this disease took a sudden change when Hebra,[6] in 1876, described what he thought to be a disseminated form of body ringworm, occurring as an acute and general eruption in form of maculæ of pale red color, with a fine furfuraceous scaling. He and Kaposi called it herpes tonsurans maculosus et squamosus. It is strange that such acute observers do not mention the annular form as we are wont to see it, according to the modern description of pityriasis rosea. From this time on the path of pityriasis rosea became a troubled one. The first to take up the gauntlet against its parasitic nature was Horand[7] in Lyons, 1876. He describes seven cases in children, resembling pityriasis rosea and corresponding with Hardy's description of the disease. He declares it to be of non-parasitic nature, although two brothers who slept in the same bed had it.

The contemporary literature shows only a few and solely French contributions. In 1877 Vidal,[8] who called it erythéme desquamatif pseudo-exanthematic, and Metton;[9] in 1880 Nicholas,[10] whose description rather fits eczema seborrheicum psoriasiforme, published accounts of the affection. In 1881 Oatman[11] published his case resembling tinea versicolor, except that it was brighter and redder.

Behrend,[12] in Berlin, 1881, was the first German author to write on this subject. He declares pityriasis rosea an independent disease, not extremely rare and most probably of parasitic, although not of trichophytic origin. He wants it to be termed roseola furfuracea herpetiformis. In 1882 Vidal[13] describes a parasite found in the scales of pityriasis rosea which he calls microsporon anomoen or dispar; the pathognomonic significance of which is, however, much contested.

The literature on this topic now became somewhat more extensive concerning the entity of pityriasis rosea. Hans[14] describes a case where a whole family developed pityriasis circinata from a trichophytic dog. From this he tries to establish the identity of both diseases. In 1882 Weyl[15] pleads for the independent standing of the

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, W. L. Baum and J. A. Fordyce.

affection, and Behrend[16] again emphasizes that it is not only different from ringworm, but coincides with Vidal by believing in a parasitic and non-parasitic form of the disease.

In 1882 Jamieson[17] calls it an imitator like most skin diseases. In 1884 Colcott Fox[18] describes the affection in children and establishes Gibert's claim of priority. In 1885 Chapard[19] and Kinnier[20] wrote on this affection, and Ferrari[21] coincides with Vidal as regards the presence of his parasite.

Blanc,[22] Bulkley, Fox and Robinson[23] describe this affection, being doubtful as to its origin. In 1886 Jaquet[24] writes of this disease as having some connection with gastric dilatation. In 1887 Brocq[25] published his celebrated article in which he draws attention to the so-called "herald patch" as a distinctive diagnostic sign. Peroni[26] observed a small epidemic of herpes tonsurans maculosus et squamosus Kaposi, which he thinks to be a roseola furfuracea trichophytica. He alleges its contagiousness, which is, however, open to doubt. In 1888 Boeck[27] speaks of the disease, and Unna[28] touches on the relation of pityriasis rosea to seborrheic eczema.

In 1899 Barduzzi[29] describes three cases with no fungus found; his inoculation experiments, as did Weyl's and Koebner's, proved negative. Moingeard[30] regards it as a general infection with a cyclic course. Jaquet[31] again emphasizes its connection with gastric disturbances, and Besnier[32] points out the analogy existing between pityriasis rosea and eczema seborrheicum and its coincidence with gastric disorders. Fournier[33] dilates on a case, persisting four years, remarkable for the confluency of its lesions. Feulard[34] thinks dilatation of the stomach to be an etiologic moment. Hallopeau[35] relates a case of four years' standing and von During[36] declares it to be an independent disease. Mracek[37] describes a case of herpes tonsurans universalis complicated by polyarthritic rheumatism. In 1890 Thibierge[38] enlarges on the importance of the Fournier "medallions," and gives an excellent histologic résumé. Köbner[39] mentions a case in a syphilitic with mucous patches of the pharynx, finding micrococci; to which, however, he does not attribute any etiologic dignity.

In 1891 Moingeard[40] regards it as a general infection. Tenneson[41] reports a case of six months' standing. Lefevre[42] describes a case where the eruption did reappear intermittently on the same places.

In 1892 Lassar[43] states that many eczemas of unknown origin are caused by pityriasis rosea being irritated by treatment, and touches on its mechanico-chemical etiology. Havas[44] cites a case of herpes tonsurans maculosus with fungi of trichophytosis.

In 1894 Oro and Mosea[45] published a very exhaustive exposé of the entire question of pityriasis rosea. In 1895 Phillips[46] reports a case of nine months' standing complicated by jaundice. In 1896 Corlett[47] gives excellent points in differentiating this affection from syphilitic eruptions. Tandler[48] gives an exhaustive histologic report of the affection in question.

Sabourin[49] reports a case each of pityriasis rosea and trichophytosis cutanee, finding no fungus in the first, but finding it in the latter, and states that the two affections had nothing in common with each other. Kromayer[50] thinks it is caused by extraneous agents. In 1899 Rasch[51] writes on the topic, and Blaschko[52] points out that in pityriasis rosea there is exfoliation from the center to the periphery, while in psoriasis desquamation takes place from the periphery to the center. Fournier[53] regards it as a pseudo-exantheme of non-contagious character.

In 1900 Hollmann[54] and Loewenbach[55] render up-to-date histologic contributions, and Levallé[56] describes it as a constitutional affection like syphilis. Fiocco[57] regards it as of endogenic origin of toxic nature. In 1902 Sabouraud[58] furnishes an excellent histologic description.

ETIOLOGY AND PATHOLOGY.

The etiology of pityriasis rosea is considered uncertain. There is a tendency at present to regard it as a constitutional affection. The earliest observers thought it to be dependent on an arthritic or herpetic diathesis and classed it among the "arthritides pseudo-exanthematiques." (Gibert, Hardy, Bazin.)

A minority of observers, however, think it to be of mycotic origin. Hebra, Kaposi, Hans and Havas hold the eruption as identical with herpes tonsurans maculosus et squamosus, and consequently of trichophytic origin. Behrend and Weyl regard it as a parasitic disease of some kind. Vidal holds his contested microsporon dispar to be the causative factor, and Ferrari coincides with him. Bulkley and Lustgarten[59] lean towards its microbic origin, and think that all cases are not identical in their etiology.

The frequent coincidence of pityriasis rosea with gastric disturbances can not be ignored any longer or looked on as accidental. Excellent observers have recorded such a combination. Jaquet found it combined with gastric dilatation and cites Bouchard, who found pityriasis rosea five times in patients so afflicted. Feulard and Besnier attribute a causative influence to gastric dilatation, and Tenneson alludes to the fact that other dermatoses are also caused by gastrointestinal disturbances. Phillips have seen a case of nine months' standing, complicated twice by jaundice, and Allen[60] reports cases with acute or chronic digestive derangements, and also a case of an habitual drunkard, who had seven attacks, especially after swearing off, which seemed to disturb his digestive organs. Fordyce and Piffard[61] regard it as caused by a parasite of unknown origin. Fiocco states that in seventeen patients having had this affection the urine constantly contained peptone and indican and that its toxicity was greatly increased. Moingeard already regarded it as a general infection. Sherwell[62] in his cases noticed a rheumatic tendency and has seen it associated twice with the puerperal state. Fox and Jackson[63] regard it as non-parasitic. Stelwagon, Crocker, Hyde[64] look on it as a disease *sui generis*.

My cases also suffered from various chronic stomach disorders, and some of them reported having had acute gastric disturbances when the eruption first appeared. Besides this affinity between stomach disorders and pityriasis rosea, most authors concede the existence of systemic disturbances, due to some micro-organism, absorbed by the circulation and distributed on the skin (Crocker). The sudden outbreak, the character of the eruption, its non-contagiousness, its cyclic course, diffuse distribution, the mode of its appearance and its rare recurrence, all point toward the opinion that the disease in question is of endogenous origin, most probably transmitted to the skin by autointoxication. Although recurrences have been reported by Allen, Fiocco and a few others, yet this would not vitiate against the disease being of endogenous origin. In rare instances we find a recurrence of smallpox, or measles also, without questioning in the least their endogenic origin.

Those who yet believe in its extraneous causation deduce their views from observations contestable. According to Lassar, Hutchinson, Kromayer, it developed after the donning of new, unlaundered underwear, or from old

underwear that had been kept in ill-ventilated places. Their cases occurring mostly in the spring and fall when such a change in wearing apparel usually takes place, they look on pityriasis rosea as a seasonal disease of extraneous origin. Lassar reports a case where the pressure of a defective spring from a truss caused the eruption.

Kromayer has seen a case develop on both legs after putting on new stockings. Bulkley[65] observed a case in an attendant at a Turkish bath; so did Allen,[66] whose patient had a number of recurrences, though constantly undergoing steaming and washing of the surface. It can be seen from these few selections that a chemical or mechanical irritation, especially of textile fabrics, is looked on as an etiologic factor. Lassar has seen similar irritative conditions to cause or aggravate lichen, eczema or psoriasis.

To refute this assumption I may be permitted to state that irritation may cause, in persons so disposed, an eruption of some kind or resembling the one already existing. We all know the proneness of syphilitics to evolve on irritation kindred lesions to those already existing. Syphilis and irritation is a caption well known to us. The condition called urticaria factitia, where mechanical irritation of the skin provokes red elevations with pale centers, simulating symptomatic urticaria almost absolutely, is another instance of mimicry of skin lesions through outside influences. But we are not authorized to say that these mechanical irritations play the rôle of an etiologic factor. Here the vasomotor disturbance of the skin predisposes it to respond in this peculiar way and not the action of the finger nail or lead pencil which does the provoking scratching.

Some people may possess a latent disposition to develop pityriasis rosea, an eczema, a lichen or a psoriasis; they may in a manner have developed already—probably yet unnoticed—initial lesions of their kind, when a casual mechanical or chemical irritant will furnish the necessary impulse for the spreading of an already existing or the provocation for certain new lesions. Here, again, the disposition is the etiologic factor and not the provoking irritant.

I therefore think the theory that a chemical or mechanical irritant alone will cause pityriasis rosea to develop is untenable. Beside, in a case of pityriasis rosea recently observed by me, where an abdominal bandage was worn after an operation for appendicitis, it was just the area covered by this bandage which was devoid of a single lesion.

As to the cases of the bath attendants, I think the constant steaming and washing served as the provocative agent to these individuals so predisposed. A mycotic process would surely have yielded to the continuous cleansing procedures to which these people were exposed. Besnier[67] has shown that the most diverse pathogenetic elements may cause identical erythemas, a proposition which everyone of us has no doubt verified. Provocation of lesions similar to already existing parent lesions are frequently observed. I have repeatedly elicited lesions of lichen planus in patients so affected by a slight scratch of a needle.

As to the contagiousness of the disease, this has been thought of only in connection with a parasite ab extra. I have dwelt on this point in the etiology, but will mention a few more cases, which seemingly point towards the contagiousness of the disease.

Crocker[68] observed two cases in a family, Zeissler[69] in a husband and wife, Fordyce[70] in husband and wife and two sisters, Fox[71] in mother and child, but regards it as accidental; Johnston[72] in a boy 5 years old, where the throat showed eruptions identical with those of the skin, even to the scaling. The fact that different members of a family had the disease is not proof conclusive of its contagiousness. The few cases occurring in families are *nil* when compared to the promiscuous appearance of the disease in general. In families the same environment, the same food, similar habits prevailing, may cause similar diseases, without taking recourse to contagion. The disease is known to have occurred in small epidemics among people in different walks of life.

I had a series of cases within a comparatively small space of time: within the last two weeks of my service at the German Poliklinik five cases presented themselves for treatment. All of them complained of general and three of them of gastrointestinal disturbances before and while the eruption took place. In all of them the urine contained indican, but I could not find peptone as did Fiocco. Again, it is significant, in spite of the numberless examinations by the most competent men that the presence of a fungus has not yet been revealed.

PATHOLOGY.

Philippson[73] aptly maintains that, while according to the teachings of general pathology the propagation of diseases in the system is due to pathogenic substances carried through the blood, in dermatology this mode of propagation is rarely taken into account. In the pathology of exudative erythemas their vasomotor origin and angioneurotic character are usually emphasized. But it is equally true that the metastatic theory offers a more natural and tangible explanation. This is under certain restrictions true. It is the transmission of irritant substances to the skin, the alterations in the walls of the vessels that cause the erythema lesions. If pityriasis rosea be a skin affection of exogene (mycotic) origin, the irritation ab extra would surely cause a more active inflammation of the epidermis; but, being of endogene (toxic) origin, the mild changes in the upper strata of the skin are explained. The irritative substance on its way from the blood to the surface undergoes certain alterations, satisfies certain affinities, is attenuated, as it were. The process will invade the deeper strata of the skin first and, expending its force, the main lesions will be found there.

If pityriasis rosea be a mycotic disease, this external irritant would invade the upper strata of the skin first, causing there the main anatomo-histologic changes to appear. But this is not the case here, because the erythematous macule has its starting point from within outward. On the other hand, ringworm works its way from without inward. This conception of the evolution of pityriasis rosea makes the seeming incongruity of Loewenbach's studies better understood. He has found in pityriasis rosea, with its clinically mild symptoms, more profound histologic changes in the cutis than in ringworm of the body where the clinical symptoms and the epidermic changes are of a more formidable character. This means that the milder pityriasis rosea affection is combined with deeper histologic changes and the severer affection—ringworm—with milder ones. Of course, as the process advances, ringworm will show deeper histologic lesions also. And there will be a period where an older lesion of ringworm will histologically resemble a recent lesion of pityriasis rosea in the deeper structures.

It is of only secondary importance for our purpose whether this erythema is caused by vasomotor disturbances or by vessel alterations. The main factor is that

the maculæ of pityriasis rosea are of an erythematous character clinically as well as histologically.

According to my histologic findings, the local lesions of pityriasis rosea are caused by the alterations of the vessel walls, produced most probably by the circulating toxins. This is what Philippson has found to be the case in erythema. Török and Vas,[74] who also contest the angioneurotic origin of urticaria, maintain that erythematous alterations of the skin are nothing else than the reactive irritation phenomena of the vessels. I would add that erythema is the simplest kind of inflammation, an inflammation of a very mild type, a metastasis caused by the alterations of the walls of the vessels of short duration.

Pityriasis rosea shows clinically only congestive hyperemia of oval or circular maculæ of pale red color, shading off towards the center into yellowish red, paling on pressure; and histologically emigration of leucocytes, edema of the cutis and no perceptible change in the epidermis, with only slight furfuraceous scaling. While in the typical inflammations graver tissue and epidermic changes are present. Such lesions have a brighter color, do not fade on pressure, do not show the particular changes of hue in color; they show infiltration and desquamation on a highly inflamed basis. Mracek[75] remarks that strict proof has not been adduced yet whether an angioneurotic process can not eventually cause inflammatory changes in the skin.

In applying these enumerated characteristics to pityriasis rosea we must concede that the affection is of an erythematous character and, like all erythemas, of endogenous origin. The pathogenic substance may have been produced either in the system or carried into it from outward sources and then transported by the blood current into the capillaries of the skin. From these conditions erythematous lesions result.

SYMPTOMS AND DIAGNOSIS.

After what has been said previously little remains to characterize the symptoms of pityriasis rosea. The clinical picture presents at first small flat papules of variable size, out of which develop discreet, barely elevated, moderately irritable, oval or round maculæ. The color is of reddish or pale red or salmon tint, and paling on pressure.

Just the same as the histologic picture, so the clinical form and color differ with the age of the lesions. As the maculous circinate and annular forms present different evolutions of the original type, so the tint accompanying each stage will be different according to the age of the lesions. It will vary from a pale red or salmon to a dull reddish color of the fully developed lesion. Fading begins in the center, extending towards the margin and lending then a grayish tint, like milk-coffee to the vanishing eruption.

The margins of the lesions pass imperceptibly into the surrounding healthy skin. There is no vesiculation, exudation or papulation present. By peripheral extension and central subsidence the annular variety is produced.

But even this annular variety hardly shows a palpable border. The discs fade off in the center to a pink, and in the ringed variety, through central involution, a wrinkled or shriveling minutely radiated center is produced (plissé), which lies within an oval border of a roseate zone, lightly scaly towards the margin. This configuration represents Fournier's "medallions." About two weeks after the appearance of the "herald patch," the whole trunk becomes covered with innumerable spots, discs and circles; a profuse eruption like that of an exanthema taking place all over the body with the exception of the hands, feet and genitalia, which are almost never involved. Sometimes the maculous form alone supervenes, but mostly the macular circinate form is represented. The appearance of the eruption, however, does not always show this—so to say—classical type. In rare instances it shows up in a rudimentary way, exhibiting only scarcely visible spots of dull red macule, especially in the axillary regions. I have seen a case of follicular involvement, somewhat greasy to touch, resembling eczema seborrheicum. At first the lesions do not show any scaling, but later fine furfuraceous scales appear. *On scratching a recent not yet scaling patch with the finger nail, invariably some scaling can be produced in its center, which is the more surprising, as there was apparently not the slightest indication of such.* I regard this sign as *pathognomonic,* as I could not elicit it in any other lesion of an erythematous character. With its help we were enabled in our class to diagnose the eruption in its earliest stages, verifying it later in every instance. The explanation for this strange condition is found in the histologic change of the rete cells. The slight intercellular compression which the edema exerts on the succulent rete cells is not strong enough to cause desiccation of them in their upward move. Later, when a more abundant parvicellular infiltration has taken place, the regeneration of the epidermis cells and with it their desiccation and following desquamation will be a livelier one and a spontaneous desquamation will ensue.

A very useful help to diagnosis is the "herald patch," "plaque primitive" of Brocq, "plaque maitresse" of Besnier, our primary or parent spot. This is a hyperemic disc with a tawny yellowish center, of various dimensions, from the size of half a dollar to several inches in diameter. However, it is not present in every case. But, as it appears about two weeks before the general eruption breaks out, and as patients rarely present themselves before this time, there is a strong possibility of its being overlooked. I have seen it only twice in fourteen cases; once under the right clavicle and once in the left epigastric region. Allen[76] observed it occupying the whole chest wall. Behrend under left clavicle, assuming an annular form, and on the left sterno-mastoid region. Fournier on left forearm. Fordyce on abdomen, etc.

This primary lesion, appearing two to three weeks before the general eruption sets in, lends the disease, as to its evolution, a resemblance to syphilis. It has a primary lesion, an acute course, spontaneous involution and is often associated with slight systemic disturbances, like rise of temperature, anorexia, etc.

One of my cases presenting itself at my class, and in which the face was also affected, showed quite grave catarrhal symptoms—conjunctivitis, coryza, puffed face, reddened tonsils and swollen cervical glands accompanying the acute development of the affection. These acute symptoms usually cease as the eruption has established itself. But, in most of my cases, I have heard complaints of lassitude and more or less discomfort up to the time when the eruption commenced to fade away. Itching did not annoy my cases enough to complain of it.

I will only mention a few of my cases cursorily:

CASE 1.—J. M., 22 years old, presser, presented himself at the German Poliklinik with an eruption showing dissemination over trunk, arms and legs, including face, of rosy spots and circles, not raised over the level of the skin, with slightly furfuraceous scaling. The youngest maculæ do not show scaling, but slight desquamation can be elicited by scratching. Complains of general malaise, face somewhat puffed, eyes suffused from a conjunctivitis. Microscopic exam-

ination revealed no fungus, only the common microspores of the skin.

CASE 2.—L. M., 26 years old, private patient, traveler, healthy looking individual. Shows general eruption of a macular and circinate form on the trunk, front and back, on upper thighs, and a few on the crures. Face not involved; pretty lively desquamation. The very intelligent patient complains of lassitude before and since the outbreak of the eruption. He distinctly remembers having had stomach and

Fig. 1.—X 125. Showing spindle cell inflammation around vessels in the papillæ and also lower down in the cutis, edema in rete fairly well preserved, stratum granulosum, and separation of cells in stratum corneum.

intestinal disturbances previous to the appearance of the eruption. No fungus found. Remembers herald patch under left clavicle about ten days before eruption.

CASE 3.—L. B., 24 years old, upholsterer. When presenting himself at my class, he had the eruption for three weeks, disseminated over the whole body down to the ankles, also on face. On neck, coalescing maculæ and segments of rings, very

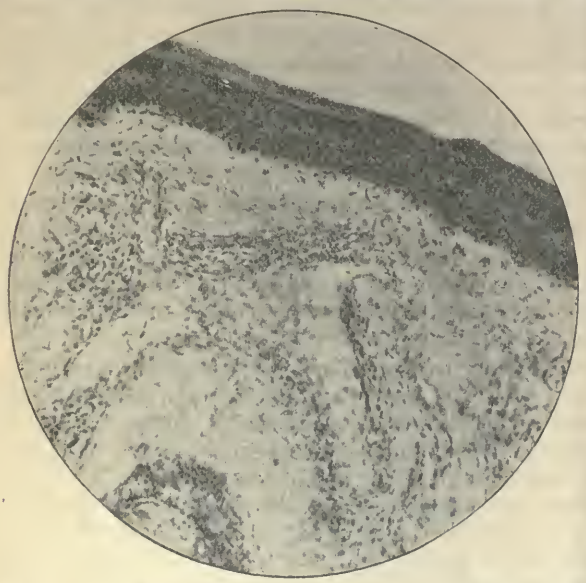

Fig. 2.—X 125. Showing spindle cell inflammation around small vessels in a papilla, and the vessel filled chiefly with white blood cells. The entire epidermis is well preserved.

irritated—most probably from collar—raised and accordingly very scaly. This case exhibits the most abundant desquamation in all my observation. Patient has a few maculæ on buccal lining, distinctly characterized by their redder appearance from the surrounding mucosa. No syphilis. Very light smoker. Remembers no herald patch, but complains of chilly sensation, loss of appetite and weakness, which enables him to work only half time. When the eruption appeared he had a sore throat, whether coincidentally or not can not be decided. No fungus.

CASE 4.—A. M., 36 years old, teacher. Presented himself at my class and shows a general maculous, only rarely gyrated eruption of three weeks' standing, disseminated especially on chest down to the pubis and on back. Face not involved, neither are extremities. Slight itching. Remembers herald patch to the left of the navel about four weeks ago, which he

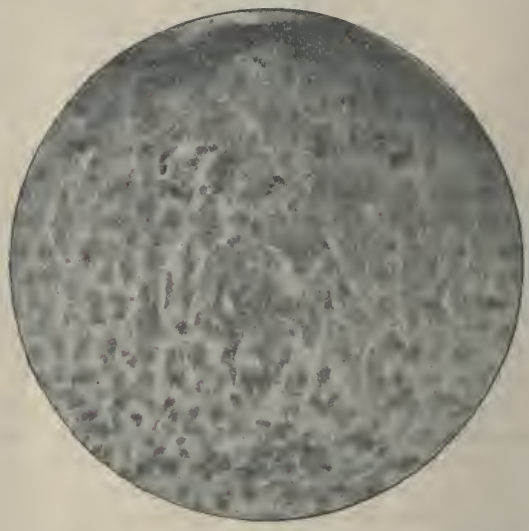

Fig. 3.—X 350. Shows how the products of inflammation in the papillæ break through into the corium. The intercellular edema is very marked.

thought to be of no further consequence. About two weeks ago he felt general malaise and, as his children were down with measles and his throat was somewhat irritated, he had himself examined elsewhere and found, to his dismay, an eruption which was thought to be measles. On examining him, I found no temperature, no cough, no other objective symptoms besides the eruption, which was vanishing in some and appearing in other places. Some furfuraceous scaling. On macule not yet scaling, such can be elicited as usual by scratching with finger nail. Beside slight itching, no subjective symptoms. No fungus.

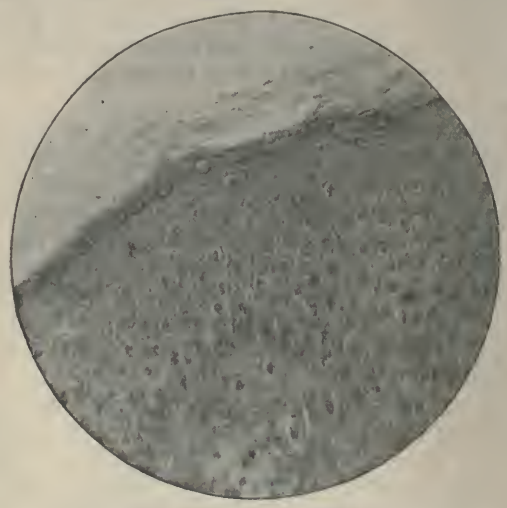

Fig. 4.—X 350. Shows how fine exfoliation takes place which appears as scales clinically, stratum granulosum not much altered, prickle cells and intercellular edema; inflammation in the papillæ.

I will not enumerate any more cases, of which I had fourteen in my service and two in private practice within four months, as they do not show any aberration from the well-known clinical features. When possible, a piece of skin was dissected and histologic examination was made. From the scales, cultures were sown out, which, however, in every case proved to be negative.

MICROSCOPIC REPORT OF PITYRIASIS ROSEA.

1. The examinations of scraping (epithelial scales) from the eruption proved absolutely negative as to the finding of any fungi, both by the direct examination of the scales and by cultural methods on potatoes, bread and water, nutrient agar, etc.

2. The examination of sections made from the extirpated tissue did not reveal the presence of any fungi when stained according to the most approved methods of Waelsh, Unna, Sahli, etc.

3. The histologic examinations of the specimens seem to give much more information as regards the pathology of the disease.

The picture is one of an inflammation, characterized by a proliferation of spindle cells around the blood vessels in the cutis, besides the ordinary change of a mild exudative inflammation, viz., emigration of leucocytes, exudation of serum and diapedesis. (Fig. 1.)

In the early stage of the disease (macular eruption) this spindle cell formation can already be noticed around the blood vessels. (Fig. 2.) In the more advanced stages this spindle cell formation is very characteristic. As this process takes place around all the small-

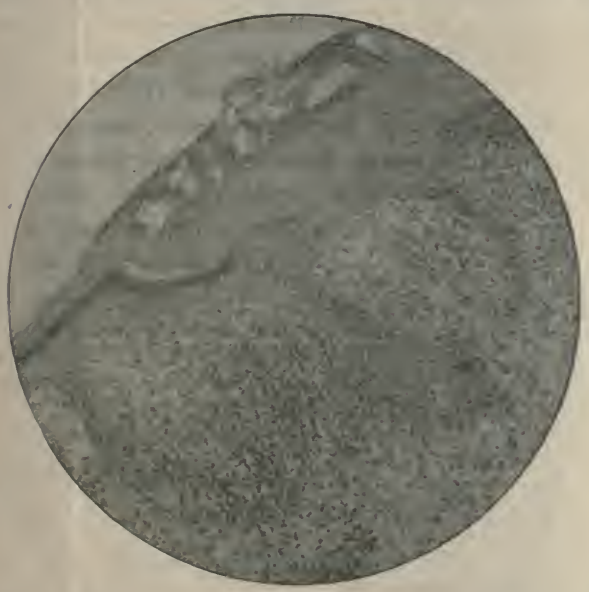

Fig. 3.—X 125. Herpes tonsurans corporis. Shows great changes originating in epidermis, with secondary round cell infiltration just beneath corium. (*By courtesy of Dr. Max Joseph, Berlin.*)

er vessels, it is at once evident how the corium becomes broken and infiltrated in many places, as the small vessels in the cutis run up in the papillæ just to underneath the corium. (Fig. 4.)

The consequence of all this is that the cutis and epidermis become edematous and appear very loose and succulent. (Fig. 4.)

In the epidermis the cells in the rete appear succulent and the lymph spaces enlarge. The stratum granulosum is well preserved except in a few places.

The stratum corneum is also edematous and the result is that there is a separation of the individual cells. This accounts for the fine exfoliation clinically. There is no tendency to the formation of vesicles. (Fig. 5.)

As the disease is not a localized one in the true sense of the word, but really a general eruption, I am inclined to look on the same as one which is due to some irritant which is brought to the periphery from within the body, the same as in erythemas, and therefore regard the condition as an erythematous disease.

To define the microscopic picture, I would say that we have a mild subacute exudative inflammation, affecting chiefly the cutis and tending toward resolution.

I will show you the micro-photograms of the specimens later, which will conclusively show their anatomo-histologic character and secure for the affection a place among the idiopathic erythematous eruptions.

DIFFERENTIAL DIAGNOSIS.

The disease with which it is most frequently confounded is the *disseminated ringworm* of the body. This is due more to a certain preoccupation and bias than to actuality, because there is no more identity between the two affections than there is between varicella and pemphigus, or between measles or a maculous drug eruption. The gross form looks somewhat alike, that is all. Herpes tonsurans maculosus and circinatus, if it should begin with a large solitary spot, will differentiate itself from the "herald patch" by its more clearly defined hyperemic outlines, its raised margin and the regularity of its circle. There is slight vesiculation around the borders and the papular element is more pronounced. The circinate ringworm does not start from so many centers and does not show symmetry and never breaks out so suddenly and profusely. As an auxiliary I may mention that circinate ringworm likes the region of the dorsum of the wrist, the region under the chin, the sides of the throat. The center of a ringworm patch which has extended towards the periphery recovers and looks normal, not wrinkled and tawny, as in pityriasis rosea. The hairs are always affected in ringworm; never in pityriasis rosea. The patches of ringworm extend centrifugally very rapidly; in pityriasis rosea they are more fixed. And last, but not least, the fungus of the trichophyton tonsurans can be found in every case, while it has never been found in our affection.

I firmly believe, as a pupil of the great Hebra and with due reverence to his master genius, that had he lived to see the evolution of our etiologic knowledge, he would have been the first in his high-minded integrity to recede from an untenable position and declare his cases of herpes tonsurans maculosus et squamosus to be what they really are—a diffuse erythemato-squamous systemic affection.

The other diseases with which pityriasis rosea could be confounded I can dismiss with greater dispatch. From *seborrheic eczema* it differs in its distribution. Here, too, the border is more raised, the lesions show a deeper infiltration, the scaling here is a more prominent symptom, the lesions are of a brighter red and have a peculiar fatty, greasy touch.

I have found seborrheic eczema to spontaneously yield scales, even in places where it is exposed to maceration, *while pityriasis rosea will do this only when scratched.* While common on trunk, its predilection of site is on center of chest and back. I have found associated with it extensive seborrhea of the scalp and a hyperemic and scaling corona seborrheica on hairline border, either entirely encircling the head or partially so, and then mostly on post-auricular or temple region. The individuals so affected are mostly anemic and exhibit the peculiar shiny greasy-gray aspect of their skins with slight general pityriasis. Furthermore, there is no such sudden development as in pityriasis rosea.

As to *roseola syphilitica,* the distinguishing points are many. And yet, men like Vidal and Fournier confess to having mixed up pityriasis rosea with it, and that only the characteristic medallions helped them to make a diagnosis. It is with the *early syphilide* and not with

the later manifestations with which it is most frequently confounded. Many lightning cures of alleged syphilis are attributed to the skill of the medical attendant and the administration of mercury, where nothing else than a natural involution of pityriasis rosea lesions has taken place.

The macular syphilide is also a general eruption, but it is redder and does not show the roseate hue of pityriasis rosea. Neither is the salmon color of the center present, nor does its center clear up at all, but the whole lesion fades away simultaneously without forming circles. In the syphilitic lesion the papular element is more pronounced; there is clinically and histologically a higher type of inflammation present. Scratching of a macule with the finger nail does not elicit, like in pityriasis rosea, fine furfuraceous scaling; neither is there spontaneous scaling present. In the late secondary annular syphilide we find the lesions absolutely elevated above the surface of the surrounding skin, infiltrated, of high red color, but scaling very scarce and elicited only with difficulty by scratching. Although exceptional, the throat may be slightly affected in pityriasis rosea—in syphilis we will always find acute disturbances of the buccal mucosa and tonsils and involvement of the glands. These points will suffice for a diagnosis, even if a history of syphilitic infection is wanting.

I may mention as an auxiliary that I have found that syphilitic efflorescences, when touched with the finger nail, always make the patient complain of pain, while on the normal skin, or in other erythematous eruptions, this interference is not felt at all.

From *psoriasis* it is easily distinguished, when the latter is well developed. A confusion can occur only in the recent punctate lesions in persons who are perspiring abundantly, or in summer, when the lesions naturally are moist. But, on scratching, we have here the punctate hemorrhages. The topography of the lesions—extensor surfaces involved with predilection—must be taken into consideration. In the so-called atypical psoriasis with anomalous localization, or in those cases where the scales do not show the white mortar-like brittle characters, but only soft, greasy, grayish-white scales of eczema seborrheicum psoriasiforme, the diagnosis may be doubtful for a moment. But here, too, the absence of a herald patch, the polycyclic evolution, the scaling, the amount of which in these atypical cases even far exceeds the most abundant scaling of pityriasis rosea, will soon clear up the diagnosis which, I am sure, will but rarely if ever confront the dermatologist.

TREATMENT.

There is hardly a necessity for such. Against the general malaise, a saline cathartic; against the anorexia or other gastric and intestinal disturbance, the exhibition of diluted muriatic acid and nux vomica will be in order. If itching is complained of, bran baths and mild salves, probably with the admixture of salicylic acid or resorcin, are to be recommended, or spirituous lotions of the same drugs may be applied.

The much-vaunted influence of higher percentuated salves with salicylic acid, resorcin, sulphur, naphthol, with a view of their parasiticidal virtues, is absolutely *nil*. There is no fungus to kill in this affection, and whatever changes these salves may elicit on the skin—bleaching and desquamation—are due to their reductive qualities of the remedies incorporated in them.

In the foregoing I have tried to add a modest mite towards the elucidation of the pityriasis question, the place of which dermatosis in the system, I hope, will soon be established beyond a reasonable doubt.

In conclusion, I wish to express my thanks to Dr. Henry Kreuder of New York City for his valuable assistance in preparing the accompanying microphotographs and histologic examinations.

DISCUSSION.

DR. HENRY G. ANTHONY, Chicago—I am perfectly familiar with pityriasis rosea and its diagnosis, and I have looked on it for a considerable length of time as a rare form of disease in my practice, but during the past year I have seen a number of cases, and discussing the subject with other dermatologists in Chicago have learned that there are a number who agree with me that the disease is decidedly on the increase and that we are now seeing more cases than ever before.

I have always looked on the disease as parasitic. Of course, in the present stage of our knowledge of the disease nothing can be said definitely in regard to this.

The result of treatment I do not lay any stress on because I have never treated it internally, my medication has always been external and the duration of the disease has always been possibly as it would have been without treatment.

As to the spot of origin, I always look for that, and in two cases recently have found it between the scrotum and the thigh. That is a location which is not usually mentioned.

DR. L. DUNCAN BULKLEY, New York—I was surprised at Dr. Weiss' mention of the frequency of this disease; it seemed to me greater than I have observed, although I see cases of it all the time. I think it most absurd that Hebra should ever have called it a diffuse ringworm. It is the most stupid thing we ever had from the Vienna School, and beyond question it has caused confusion in the minds of some people. For two or three reasons I have always been led to regard pityriasis rosea as a microbic disease. In nine cases out of ten the development is from above downward, commencing on the shoulders or neck and developing down rather than upward, which is the history of most parasitic diseases. The ringworm-like spread of the eruption has always seemed to me distinctly indicative of a parasitic element, although we have never yet identified any microbe or produced it by inoculation.

One gentleman has spoken of the treatment. I think it disappears with the use of bichlorid. No eruption of urticaria will disappear as a case of pityriasis rosea disappears under the proper use of bichlorid of mercury. I have never found constitutional treatment do any good.

DR. A. W. BRAYTON, Indianapolis—I can recall on my fingers the cases I have seen. I have been inclined to look on it as a cutaneous expression of an infective disease like scarlet fever or other members of the cutaneous exanthemata. I recall a girl of 20, in excellent health, the first case I ever saw; the others occurred in a group, one might say. I saw no more cases until within two years. I recall a healthy man of 35 or 40, next a young physician of 26 or 27, an optician of 50 years, and a healthy woman with a child five or six months old, which she was nursing. Three of these cases were promptly diagnosed as syphilitic eruptions. None of the persons was sick. I have seen six cases in my practice in Indianapolis in the last ten years, and all have been well marked, and there has been no difficulty in the diagnosis. In only one case did I determine the antecedent primitive patch on the trunk. The cases occurred in married people; there was appearance of the disease in the husband or wife of those affected.

DR. M. L. HEIDINGSFELD, Cincinnati—I am very much interested in this exhaustive and well-prepared paper, as well as the investigations of Löwenbach and a few of the other authorities mentioned. I have always felt a little skeptical in regard to the finer shades of differences which Löwenbach and others have attempted to draw between herpes tonsurans maculosus et squamosus, and pityriasis rosea. I have endeavored to confirm for my own personal satisfaction, from carefully selected cases, the pathologic differences, but have failed to note the distinguishing characteristics. I must also beg to differ with the essayist on purely clinical grounds, that pityriasis rosea has an internal pathogenesis. The fact that a fungus can not be detected in the scales under the microscope, means practically nothing. Cases of unquestioned herpes tonsurans frequently fail to show fungi. In selected cases, you may even start a dermatosis with a fungous inoculation, and though the dermatosis may continue to spread, the fungus may soon disappear, so that its presence can no longer be detected. Not only the action of the parasiticides, but also its usual origin and spread from a single patch, besides a mass of other clinical data, speaks strongly for its external nature and extraneous origin. I believe the burden of proof is strongly in favor of its external origin, and in the effort to establish an internal cause, if we invoke to our aid the sympathetic and vasomotoric systems, we are casting aside very plain and almost definite evidence for theories that are, I believe, at best, vague, indefinite, illusory.

DR. JOHN A. FORDYCE, New York—Dr. Weiss quotes me as favoring the parasitic origin of this disease. I made a statement some time ago in the Dermatologic Society to that effect, based on an observation of two cases in one family, two sisters who occupied the same room, and, I think, the same bed. That is the only instance I have had in which I could find evidence of contagion. I have observed in the last two months two cases of pityriasis rosea with atypical distribution where the lesions were chiefly on the extremities, the trunk being only slightly involved.

DR. LUDWIG WEISS, New York—I know there is a difference of opinion as to the pathogenic origin of this disease. Is it not strange that with our well-developed methods of investigation, finding bacilli everywhere, in this disease we are not able to find anything outside of the micrococci of the skin? Why can not we find the causative microbe in the scrapings? Why can not we find it in excisions and staining? The eruption appearing in families seemingly points toward its contagiousness. I have extensively dwelt on this point. Our colleague, Dr. Zeisler, and Mrs. Zeisler had it ten years ago, and at that time Dr. Hyde and other gentlemen, in discussing these cases, said there was a question whether it was parasitic or not. It was not decided, but most of the gentlemen present said it was a disease *sui generis*. The evolution of the disease from above downward is not a criterion, I think, inasmuch as we have heard from Dr. Fordyce that it appears primarily on the thighs also. A parasitic disease will not come out from so many centers as pityriasis rosea does. You will see by the photographs that it develops over the whole body. In these lesions the borders are not raised, and you will not find any microbes in the scrapings. Why does the microbe, if present, disappear on the body, and why is it so tenacious when it appears on the scalp? It is strange that the same microbe should behave so differently in different parts of the body. As to general malaise and gastro-intestinal troubles, there is no doubt that they occur coincidently, and this shows it is some systemic disturbance that causes pityriasis rosea, and that it belongs to the erythematous diseases.

As to the differential diagnosis, Fournier himself confesses to having treated a case once, thinking it was syphilis. It is really no reproach for us to say that we are in doubt, although I do not think any dermatologist will have it, because outside

of the general history of syphilis there is one pathognomonic symptom I would again like to emphasize. If you scratch with your finger nail a very recent lesion which appears red, you will, even on a perspiring skin, immediately elicit fine scales. This is a symptom you will not find in any other erythematous disease and never in the erythematous syphilid. We have tried it dozens of times, and it helped us in the diagnosis always.

The bichlorid solution does a great deal of good; it relieves congestion and causes exfoliation of the skin. From this circumstance I would not say that the eruption is necessarily parasitic. As it stands now I think the general opinion is against its parasitic nature. I think I was able to show in these micro-photographs that the disease commences in contradistinction to the parasitic affections in the lower strata of the skin.

INFLUENZA IN CHILDREN.*

WM. CARVER WILLIAMS, A.B., M.D.
CHICAGO.

It is the writer's conviction that influenza is a more malignant malady in children than is generally acknowledged (a conviction fortified by his own experience and further strengthened by material gathered among his friends and from the literature), which has led him to venture this paper.

Without being able to furnish much, if anything, that is new on the subject, it yet seems justifiable here to emphasize some of the manifestations and possible calamities which may be traced to this disease.

Influenza vera, when the victim is a child, differs from the same disease in adults in proportion to the difference in constitution, vital resistance and recuperative power. It should not be forgotten in this connection that the disease is of a markedly toxic nature. The admirable article in Ashby and Wright's work states, however, that children are less likely to have some of the ordinary symptoms, such as backache, rigors and pain in the limbs, and more likely to earache, glandular swellings and a cough resembling whooping cough. The latter is also mentioned by Forchheimer. Blackader likewise states that the invasion in children is more often insidious and slow than in adults. These statements seem to be borne out in our experience. The very multitude of its manifestations, with the ensuing difficulty in accurate diagnosis, has so confused our statistics on influenza as to render many of them misleading; yet we are probably in greater danger of under- than of over-estimating its gravity.

Washburn and Ayre report 12 cases of death from pneumonia in children, of which the autopsies showed the Canon-Pfeiffer bacillus present as the main factor in the disease in 8 of them, though previously unrecognized.

Dr. F. E. Wynekoop, of the Chicago Department of Health, in a personal interview, stated that of the 2,460 examinations made just previous to the interview of cultures from throats in cases of suspected diphtheria, 677 showed the Canon-Pfeiffer bacillus as the only pathogenic organism, while of these 677 cases, in 173 the diagnosis of diphtheria was definitely made from the clinical findings—yet the Klebs-Loeffler bacillus was not present.

Age appears to have no influence on the susceptibility of the individual, and, while very young infants are somewhat less frequently attacked, there is some question as to whether it may not be due to better protection rather than to natural immunity. In fact, there is nothing either in the literature nor in my own experience which warrants a belief in the existence of a complete natural immunity. The question of susceptibility would, therefore, appear to be one of the comparative degree to which different constitutions succumb to the disease—one child may have a so-called mild attack followed by recovery in a few days, while a brother or sister may be sick one or two months or longer. Much depends on the state of vital resistance of the victim, as in other diseases, but even more, in the writer's estimation, on the previous health of the mucous membranes. In a series of some fifty cases showing some of the more serious manifestations, he has rarely failed to obtain a definite history of indigestion, constipation, a common cold or some other previous disturbance of the mucous membranes.

Owing to the almost universal dissemination of the pathogenic organism during an epidemic, there is comparatively little possibility of accomplishing much in the way of prophylaxis at such times. And yet, because we know that the disease may be conveyed by contact, we should insist on such precaution as can be enforced to prevent this. Children should not be exposed to the contagion in the persons of other members of the family, nor sleep in illy ventilated rooms, nor breathe the vitiated air of public rooms and conveyances. Neither should they be allowed to risk contracting ordinary catarrhal "colds" from exposure. Mothers should be warned not to neglect attention to the children's bowels, and to allow them all the fresh air possible. Thus they may be enabled to resist and defeat an attack which might otherwise prove serious from this all too powerful enemy.

The division of the disease into various types for separate consideration is more or less arbitrary. The truth of the matter is, regardless of how the division is made, that every case one sees is of a mixed type. In other words, it is a case of influenza, and not of catarrh or neurasthenia—a specific infection, giving rise to various symptoms of which sometimes one, sometimes more than one, may be prominent, but of which a number are invariably present.

Those cases in which catarrh figures as the most conspicuous indication are perhaps more frequently met with. Starting with a rhinitis, or rhino-pharyngitis, the inflammation may spread either to the respiratory or alimentary tracts, or both. Wherever there is mucous membrane we may have this inflammatory reaction excited by the activity of the Canon-Pfeiffer bacillus. Thus we may find our little patients suffering from a rhinitis, a conjunctivitis, an otitis media, an inflammation of the accessory sinuses or of the pharynx, larynx, bronchi, lungs, stomach or bowels. The seat of choice for the severer forms of the infection is doubtless influenced greatly by the comparative resistance of the mucous membrane in various localities. The more nearly normal and healthy the membranes the fewer will be the grave manifestations of the disease. Hence the previously mentioned warnings in regard to the matter of prophylaxis.

The catarrhal manifestations of the disease appear, then, to be due mainly to the micro-organism itself. On the other hand, the nervous and circulatory and febrile types may be regarded as of toxic origin. The Canon-Pfeiffer bacillus, as in the case of that of Klebs-Loeffler, produces an exceedingly active and deadly toxin, capable not only of overpowering the vital organs, but of actually destroying their structure, to some extent, through degeneration. This being so, one can readily

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M. McClanahan, A. C. Cotton and H. E. Tuley.

see how multiform in appearance and how serious in extent may be the history of such cases. One need not read far into the literature of the subject to find them, reported by careful observers, of meningitis, multiple neuritis, hemiplegia, neurasthenia and various mental disturbances—of endocarditis, pericarditis and myocarditis, arteritis, hemorrhagic nephritis and various other anomalies of the circulation with their consequences. Professor Monti of Vienna adds to these a glandular class, which includes those cases in which the lymphatic and other glands are chiefly involved, with a minimum of other clinical findings. I have included this class because I have known of several cases which would fall therein.

A form of the disease, until recently too little considered, is the chronic form, first described by Filatow. Cases have since been reported by Lord, Finkler, Wassermann, Ortner and others, where as high as 60 per cent. of cases having chronic cough, for instance, were caused by influenza bacillus, as proved by bacteriologic examination, in many instances it being found in pure culture.

Relapses and sequelæ during apparent convalescence are common, particularly the former. One can never be certain even when the child is to all appearances entirely restored to health that no sequels will follow. The writer has in two or three instances seen grave troubles develop days after recovery seemed complete.

The case reports which follow have been chosen without any attempt at covering the field. Aside from their individual interest, however, they indicate how widely divergent may be the chains of symptoms in disease traceable to the Canon-Pfeiffer bacillus, as well as the severity to which they not infrequently attain. It will be noticed that they are all more or less difficult to classify according to any of the rules laid down in different text-books.

CASE 1.—Baby W., aged 5 months, was taken ill in February, 1900, with what seemed a mild attack of influenza. The attack was, however, followed in four or five days by a bronchopneumonia, which ran an apparently typical course. As convalescence from this occurred, it was noticed that the child refused all food and even water. Examination of the throat revealed a highly inflamed catarrhal pharynx and fauces. Bacteriologic examination showed the characteristic influenza bacillus in large numbers. The angina and attendant dysphagia continued, in spite of all local and constitutional treatment, for so long a time that the child was in apparent danger of immediate starvation. There was also a middle ear complication. The little patient gradually developed decided symptoms of rachitis, which persisted until she was taken into the country in June of the same year. She did not regain the normal strength of children of her age until after she was a year old.

CASE 2.—M. C., aged 4 years, had a severe primary attack of influenza, verified by culture, in January, 1902, involving the middle ear and mastoid cells. The latter, however, never became suppurative and gradually responded to treatment—leeches, icebag, etc. Though the tympanic membrane was punctured three or four times, no pus was ever obtained. When the local trouble had subsided, the temperature still remained above normal, ranging mostly from 101 to 102.5, sometimes after exertion rising to even 104. A careful physical examination revealed a heart murmur, heard most plainly near the base and transferred most strongly toward the right. No other findings. This led to a diagnosis of post-influenzal endocarditis, and the child was kept in bed for three and a half months. During this time there was no appreciable improvement, the temperature curve and the heart murmur remaining about the same at the end as they were at the beginning of the confinement. About May 1 the little patient developed some indications of chorea, which yielded readily to treatment. She was allowed to get out of bed, was sent into the country and began to improve from that time on. The temperature gradually resumed its normal status and the murmur has been slowly diminishing ever since, till at the present time, something more than a year after its appearance, it is barely perceptible. She is in every other respect apparently strong and well.

CASE 3.—Baby L., aged 8 months, taken ill during the month of January, 1900. Several other children in the family had been ill with undoubted influenza for several weeks. The little fellow became sick gradually. For several days a slight catarrhal condition of the mouth, eyes and nose had been present. Very soon he refused to eat and developed continuous fever, which was characterized by great severity. For days the temperature remained over 104, occasionally reaching 105.5 and even 106. His pulse was rapid, extremities were cold and blue, respirations were rapid and the patient showed some cyanosis. The most careful physical examination of the chest revealed only a few râles—indeed, the changes in the chest were insignificant as compared with the severe temperature range. The examination of the heart was negative. The abdomen at times was tympanitic. Food was taken in small quantities and only partly digested. The stools were thin, though diarrhea was not a marked symptom of the disorder. The ear was repeatedly examined by a competent otologist with negative findings. At another time the accessory sinuses, including the antrum of Highmore, were most carefully examined and no positive signs of disease found in these regions. After ten days of such alarming symptoms, the patient brightened, the temperature fell and he was undoubtedly on the mend. After several days of apparent improvement the patient again relapsed into the condition previously described. Two such relapses occurred. On each occasion alarming symptoms returned and it appeared that the resistance and the strength of so young an infant was hardly sufficient to withstand so severe an infection. After a course of several weeks, the patient recovered and very soon regained his strength.

The whole course of this infection was remarkable for the almost entire absence of symptoms save the hyperpyrexia and the great prostration. The catarrhal symptoms of the mouth, nose and pharynx were insignificant in comparison with the febrile condition of the child.

CASE 4.—J. R., 8 months old, taken ill about Christmas, 1899, with an otitis. During January had an attack of influenza, with typical catarrhal symptoms, followed by a pneumonitis, during which there developed symptoms of meningitis, such as retraction of head, strabismus and twitching. At this time there was nothing locally to indicate a connection between the meningitis and the ear trouble, which appeared rather better than worse. During the pneumonia the temperature ranged from 102 to 105. A typical crisis occurred, and the temperature resumed normal, or nearly so. After a few weeks the contraction of the neck abated and there followed a paresis so that the child was unable to hold up its head. This condition lasted nearly six months. There was a similar condition in all of the voluntary muscles. Reflexes were diminished. The child was three and a half years old before being able to walk.

At present, 5 years old, though he seems bright and interested in his surroundings, taking part in the games of his playmates, he is unable to talk more than two or three words. He makes his wants known cleverly enough by signs.

I have purposely omitted all mention of treatment of influenza in children, for the simple reason that my study and experience has led me to the belief that there is no specific treatment for any of its forms. The treatment is purely rational and symptomatic, and the indications can only be met as they arise. As these are so numerous and varied an attempt to cover the subject would be obviously useless as well as practically without value.

CONCLUSIONS.

I feel justified, both from experience and from perusal of the literature, in drawing the following general conclusions:

1. Children of any age, even early infancy, are susceptible to the influenza infection.

2. Repeated relapses and grave sequelæ are frequent in cases where the initial seizure is mild as well as where it is severe. Therefore, no attack should ever be considered as "mild" nor as recovered from until a sufficient time has elapsed.

3. Clinical diagnosis should always be supported by the evidence of the microscope, whenever possible, as the practical certainty thus obtained may be of great value in explaining future developments.

I desire to acknowledge no small indebtedness to Drs. I. A. Abt, J. C. Cook, M. P. Hatfield and J. W. White for their kindness in furnishing clinical histories and other data toward the writing of this paper.

58 East Forty-third Street.

DISCUSSION.

DR. R. B. GILBERT, Louisville, Ky.—I regret that the essayist has not given us the treatment. I have been looking for some article on the management of the disease and its sequelæ. I hope some one will elaborate this part of the subject. The ravages of the disease in the young are, of course, much more rapid and severe than in the adult, and often influenza is not recognized until bronchopneumonia has developed and a fatal termination has occurred. I recall a case during the height of an epidemic of influenza in our city in which the mother gave birth to a child while still in the febrile stage. The child presented the same symptoms and died in a few days.

DR. CHARLES G. KERLEY, New York—I agree that the treatment is wholly symptomatic and I do not understand how there can be a distinct method of treatment because in different seasons and epidemics it attacks by preference different parts of the body.

Two years ago there was an intestinal type in New York City, characterized by a diarrhea bordering on the dysenteric type and associated with intense prostration. This year the complication which seemed to be particularly frequent has been involvement of the ear. I have had ten cases this year in private practice in which it was necessary to perform paracentesis, and this does not represent all of the cases in which there was ear involvement. It is evident that the treatment must vary greatly with the prevailing type. One symptom which is usually prominent is prostration. I have seen two children die from the grip simply from the intensity of the intoxication, for the autopsy failed to show any lesion to account for the death. Another prominent symptom is fever, a point which has been well brought out in the paper. I have seen cases in which the high temperature could not be accounted for even by the most careful clinical examination by anything else than the grip. I am inclined to think that some of the cases reported as typhoid fever in children were really instances of grip infection. Many of these cases of grip run along for two or three weeks with hardly any symptoms but fever and intestinal disturbance. All that we can do is to carefully feed these children, control any tendency to hyperpyrexia and employ general supporting measures.

DR. P. J. BARCUS, Crawfordsville, Ind.—It has been pointed out in recent years that when there is an epidemic of scarlet fever at the same time as an epidemic of the grip, because of some possible antagonism between the two diseases, the type of epidemic of scarlet fever is somewhat milder than usual. I have observed such conditions present during the last six months in our vicinity, but I am unable to state whether this explanation is the correct one. It would be interesting to know the real facts. The recent epidemic of grip with us has been milder than usual. I do not think it is possible to formulate any general plan of treatment; it must be symptomatic because of the great variations in the type of the disease. Coal-tar remedies and indeed anything which tends to create depression should be avoided.

DR. H. M. MCCLANAHAN, Omaha—We have seen a great deal of the grip in our city during the past winter. Two symptoms, hyperpyrexia and extreme prostration, have impressed me as very important, and I frequently make the diagnosis on these symptoms. I have not had the opportunity of making the bacteriologic tests, and have, therefore, been compelled to depend on clinical examinations. I have noted that in these cases hydrotherapy has failed to control the fever as in other conditions producing high temperature. Another fact which has impressed me is the frequency of middle-ear trouble and mastoid abscess following the grip. The record of my cases shows that there are more cases of middle-ear disease from grip than from scarlet fever, and the same is true of mastoid abscess. I have adopted a treatment in a number of cases which is not at all new. It is simply the use of quinin bisulphate by suppository in doses of from six to twelve grains daily. It does not cause depression as do the coal-tar products. A few months ago I saw a case in consultation in which the attending physician was pushing phenacetin, although the child's finger nails were already blue. I remonstrated with him, insisting that such a line of treatment was very dangerous. I have seen recently a form of grip showing well-marked nervous symptoms.

DR. THEODORE J. CATLIN, Delano, Minn.—I recall a case, seen last winter, occurring in a boy who suffered a relapse. The fever kept up a long time, and the diarrheal symptoms were marked. The family called in another physician in my absence, and he made a diagnosis of typhoid fever, stating that he made this diagnosis not only on the symptoms mentioned, but on the presence at that time of a distinct eruption. I have met with other cases having skin eruptions similar to scarlatina and some of a marbled appearance. I would be pleased to hear if others have met similar skin symptoms in influenza.

DR. C. F. WAHRER, Fort Madison, Iowa—I should like to ask regarding a classification of the different forms of the grip, and also where is the anatomic seat of this disease. Some years ago, when it first appeared, it was thought that its anatomic seat was in the cerebrospinal system. We then met with the nervous and the catarrhal forms. The treatment is not satisfactory, but is symptomatic and purely empirical. If we knew the anatomic seat of this disease we might be able to suggest a more definite line of treatment.

DR. JOHN C. COOK, Chicago—In a hospital where I do the pediatric work I saw two babies die suddenly within forty-eight hours after birth, their mothers being ill with the grip. I have seen four cases of cerebral troubles this winter, all in consultation, in which the onset was as clearly that of grip as possible. In three of the cases at least one parent had the grip. A week from the time that one of the children had been seen by the attending physician I saw the case. The child was quiet and the only indication of meningeal trouble at the time was that one leg was a little stiff. Two days later the child had Cheyne-Stokes respiration, was rigid and presented the circulatory disturbances of the skin pointing to meningeal complication. Death occurred four days later. In another case, that of a baby nursing from a mother who was thought to have had the grip, the child had appeared stupid for four days before I saw it. Examination showed the pupils unequally dilated, and not responsive to light, the child totally blind. I was assured that the child had not been blind before this illness. It is still blind.

With regard to eruptions, influenza appeared in my neighborhood early in the autumn with an eruption, and the first two or three cases I saw presented an eruption closely resembling that of scarlet fever. As a rule, the throat symptoms were absent, as were also the rapid pulse and high temperature. In addition, all of the symptoms were those of grip. In the five or six cases which I allowed to mingle with the others in the family there was no spreading of the eruption to the other members, showing that the disease was not scarlet fever.

DR. J. H. HANNA, Covington, Tenn.—I saw a case presenting an eruption which I thought to be that of scarlet fever. A few months later measles appeared in the family, and the child developed the same set of symptoms minus the eruption. There was every symptom of measles at the time except the eruption, and although I looked confidently for the measles eruption it did not come. After this had subsided another

member of the family had measles. Three weeks ago the same symptoms developed and continued for several days, with all the symptoms of measles save the eruption. After the fourth day the measles eruption appeared and was well marked and typical.

DR. W. C. WILLIAMS, Chicago—I labored under a misapprehension when I prepared my paper, and consequently wrote so long a paper that it was necessary to omit many portions in the reading. This accounts for certain omissions to which reference has been made. There can be no question that the infection gains entrance through the mucous mmbranes just as in diphtheria. Some of the German investigators claim to have discovered the germ in the blood itself, and on the valves of the heart where there had been an endocarditis, but the evidence presented is not conclusive to my mind. I had an interesting series of four cases of eruption to report, in three of which the eruption closely resembled the rash of scarlatina. However, other children did not contract the disease. Along with this rash there were not the usual symptoms of scarlatina. All of these cases happened to be followed by an acute general adenitis, indicating that it was a sequence to whatever infection attacked the skin. With regard to treatment, I can only repeat what I said before, i. e., a bronchitis or an enteritis or other manifestation should be treated just as if there were no grip element. I would suggest the use of antiseptic douches to the mucous membranes, although admitting that the trial of this measure has not given encouraging results.

THE TREATMENT OF SCARLET FEVER, ITS COMPLICATIONS AND SEQUELÆ.*

H. M. McCLANAHAN, A.M., M.D.
Professor of Diseases of Children, College of Medicine, University of Nebraska; Physician to Child's Saving Institution and Methodist Hospital.
OMAHA.

It is difficult to discuss intelligibly the treatment of a disease having such wide variations in its clinical manifestations. In speaking of the cases, I shall use the designations: malignant, mild, severe and septic. Malignant cases are those overwhelmed by the poison and terminating fatally in one or two days. I shall say nothing of the treatment of this class. Mild cases are those presenting the characteristic symptoms without complications, the fever subsiding in from five to seven days. Severe cases are those having high temperature, profuse rash, often nervous symptoms, erythematous sore throat, but without membranous exudate. Septic cases are those presenting the symptoms of scarlet fever and, in addition, membranous exudate on the tonsils and other portions of the throat. These cases may or may not be severe at the inception. This is the class of cases in which we have the streptococci infection. These clinical divisions are simply made to indicate the kind of treatment more clearly. The subjects of quarantine, the isolation of the patient, the preparation of the room and the care necessary on the part of the attendants, while important, will not be considered in this paper. Certain general principles of treatment apply equally to all cases, and to these I shall first call your attention.

DIET.

To my mind the diet is exceedingly important and not rightly appreciated. For some years I have adopted the rule of keeping all patients on a liquid diet for not less than four weeks, the object being the prevention of renal complications. According to my observations, this sequela usually follows the mild cases. During the last year I have seen five cases of nephritis following the mild forms of scarlet fever. These cases were not under my care during the acute attack. On the other hand, I have not observed this in any case where the principles of treatment indicated were faithfully carried out. By a liquid diet I mean milk, properly modified to suit the age of the patient. Many cases can be continued on this simple diet. In others we may vary it by the use of thin broths and fruit juices. In young children it is possible to modify the milk to suit almost every case. I have seen but two exceptions; for these whey was substituted with satisfactory results. In all cases the patients should have an abundance of water. In order to encourage the taking of food I recommend the use of carbonated waters, weak lemonade, orangeade, etc. I wish to emphasize the point that this diet is to be continued the full four weeks and not the first or second week, as it usually recommended. The continuance of the liquid diet during the period of convalescence is, to my judgment, the key to the situation.

REST IN BED.

The second general principle of treatment is to require that the patient be kept in bed during the entire course of the disease. I am aware that this is exceedingly difficult in mild cases, but, in my judgment, these are just the cases requiring this extreme care. The patient out of bed by the end of the first week and having the freedom of the house is more likely to be exposed to changes of temperature, to draughts of air, etc.; the influence of this exposure on the cutaneous capillary circulation adds to the work required of the kidney, and increases the danger from this source. In the severe cases it is not difficult to keep the child in bed, and I have a conviction that this is one reason why fewer cases of nephritis follow this severe form of scarlet fever.

LOCAL AND OTHER MEASURES.

In the mild cases, diet and rest in bed constitute the most important part of treatment. A spray or gargle of some mild antiseptic should always be used. Dobell's solution, properly diluted, or Seiler's tablets, dissolved in water, usually meet the indication.

I have very little confidence in any local treatment preventing otitis media. In my observation this complication occurs as frequently in mild as in severe cases. The bowels should be moved freely at the beginning of the attack and as soon as vomiting has ceased some mild aperient should be given. The bowels should move regularly during the entire course of the disease. The initial vomiting seldom requires special treatment. In cases where this is an early symptom, all food should be withdrawn for twelve to twenty-four hours. A simple fever mixture of liq. ammon. acet., properly diluted, may be given for the first few days.

ANTIPYRESIS.

Severe cases require more active treatment. When the fever is 104 it should be controlled. I have no doubt that the nervous manifestations are due to high temperature, as well as to the infection. Among antipyretic remedies, hydrotherapy ranks first. It is not only generally most efficient but, more important, it is the safest. However, in private practice the prejudice of the laity frequently prevents its proper application. Sponging with cool water is sometimes sufficient. More efficient, however, is the application of a towel dipped out of warm water about the body of the child, then, over this, is applied several thicknesses of a towel, wet with cold water. Should these means prove inefficient, I next em-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M. McClanahan, A. C. Cotton and H. E. Tuley.

ploy the cooled bath. An ordinary wash boiler, half full of warm water, is placed beside the bed. Over this a sheet is thrown. The child is immersed, the sheet preventing any undue shock and lessening the fear of the child. Gentle friction of the body is now employed, then an attendant adds a quart of cold water and removes a quart of the warm water. This process is continued until the temperature of the water is reduced from 100 to 70, in the course of a few moments. The child may remain in this bath from eight to fifteen minutes. The body is then wiped dry and the child placed in bed. Among antipyretics, I prefer sodium salicylate; two or three grains may be given every hour. This will usually moisten the skin and lower the temperature.

SEDATION.

In some cases extreme restlessness, especially during the first two or three days, require attention. I think it wiser to relieve this symptom than to permit the child to waste its energy by tossing about. To meet this indication I prefer chloral hydrate; two grains every two hours for four or five doses will usually insure quiet sleep. If the heart's action is rapid or weak this remedy may be guarded by the addition of digitalis, one to three drops of the fluid extract being given with each dose of the chloral. If, in addition to the restlessness, there are nervous symptoms, as rolling of the head, oscillation of the eyeball, indicating a disturbance of the high nerve centers, applications of the cold compress to the head are indicated. If the ice cap is not accessible, I use the ice poultice. This is made by spreading dry flaxseed meal over a piece of cloth large enough to cover the head, then distributing over this cracked ice and covering all with a piece of gauze.

TREATMENT OF THE THROAT.

In the septic cases there is a membranous inflammation of the throat and nasopharynx, with increased action of the muciparous glands. These mucous membranes present a large absorbent surface richly supplied with lymphatics, and in these cases we have enlargements of the surface of the gland, continued fever and a general infection. In these cases treatment of the throat and the nasopharynx is extremely important. In my experience there is no treatment so efficacious as irrigation of these parts with a warm salt solution. This is to be accomplished by means of the fountain syringe. It is usually better to wrap the child in a sheet so that it will be completely under the control of the attendant. I personally supervise this treatment, at least for the first time. The mouth and throat are first to be irrigated; when irrigating through the nose the mouth must be kept open. It is my opinion that fluid is not driven in the eustachian tube unless the patient attempts to swallow during the treatment. If the jaws are kept separate deglutition can not take place. The amount of purulent material that is washed away in some of these cases in a single treatment is remarkable. These treatments are to be repeated according to the exigencies of the case; two or three in twenty-four hours, for two or three days, are usually sufficient. I have seen the temperature drop two or three degrees after this treatment. In cases where the discharge from the throat and nose is fetid, the use of permanganate of potassium, five grains to the pint, is of benefit.

In the septic cases, stimulants are always indicated and should be given frequently and at regular intervals. The condition of the heart should be our guide in the use of strychnin or other cardiac stimulants.

CARE OF THE SKIN.

The skin should be carefully treated in all cases. The use of oily applications is of benefit in hastening desquamation and in preventing the infection of the room. In some cases itching is a symptom so annoying as to require attention. For the relief of this symptom my patients have received the greatest benefit from a 1 per cent. solution of carbolic acid. If this fails then the lead water solution liq. plumbi acet., 1 gram to the pint, may be employed. When the fever has subsided the patients should receive a daily bath with soap and water in order to remove the dead epithelium. This treatment is to be continued until desquamation is complete.

GLANDULAR INVOLVEMENT.

Inflammation of the cervical glands occurs in all septic cases. There is little to be gained by treatment except to add to the comfort of the patient. I am in the habit of using the belladonna salve and sometimes over this the ice poultice. Suppuration of these glands occasionally takes place and adds greatly to the gravity of the case. Treatment is surgical. Cellulitis is a serious but rare complication. I have met with but two cases. It is usual to make several incisions in order to promote drainage.

JOINT AND HEART COMPLICATIONS.

Scarlatinal arthritis is usually manifested in older children and young adults. In my experience the wrist and elbow joints have usually been involved. I have seen two cases of suppurating arthritis, one of them terminating fatally as a result of the general infection. The affected joints are usually very painful. The treatment I have found most satisfactory is the application to the joint of a salve composed as follows, sodium salicylate 1 dram, lanolin 4 drams, simple ointment 4 drams. This is thoroughly applied to the joint; which is covered by a layer of cotton batting, held in place by a roller bandage.

The heart should be carefully watched in all cases of scarlet fever. The possibility of inflammatory lesions, both endocardial and pericardial, should be recognized. I have recently lost a case from heart failure at the end of the second week. A rapid pulse, after the subsidence of the fever, or a weak second sound, should place us on our guard.

AURAL PROPHYLAXIS.

The treatment of otitis media is more important than many seem to think. Involvement of the middle ear is due to extension of inflammation along the eustachian tube. It is usually purulent, and when so the pus finds an exit through the external meatus, because of rupture of the membrana tympanum. The symptoms of the middle ear trouble are often vague. If old enough the child may complain of pain or it will be noticed to pull at the ear. Sometimes, however, the first evidence of ear trouble will be the appearance of pus in the external canal. The operation of paracentesis, while theoretically correct, is seldom employed in private practice. A careful examination of the ear should be made in all cases of scarlet fever. When the membrane has been punctured or when it has ruptured, prompt treatment should be instituted. I have for a number of years adopted the following plan of treatment. The attendant is provided with two medicine droppers, a warm boracic acid solution is prepared, the child is placed on its side with the affected ear uppermost. The dropper is filled with the solution which is gently instilled into the ear. The attendant takes the second dropper and, by compressing the bulb, withdraws the fluid from the

ear. This is repeated frequently and until the canal is free from pus. Then the ear is filled with a 50 per cent. solution of peroxid of hydrogen to which a little bicarbonate of soda has been added. This is again washed out by the boracic acid solution, and the canal gently dried with absorbent cotton. This treatment is repeated from two to four hours and continued from day to day until the discharge ceases. Involvement of the mastoid cells has not been frequent in my cases of scarlet fever. When it does occur, prompt incision with drainage is indicated.

Scarlatinal nephritis is the most important sequela of scarlet fever. In all cases frequent examination of the urine should be made. We can usually have warning of impending danger. The earliest symptoms of the nephritis are swelling beneath the eyes or on the dorsum of the foot, with a lessened quantity of urine. The treatment of this sequela in the early stage and its prompt recognition are important. The important points of treatment are rest in bed, a liquid diet and the avoidance of stimulating diuretics and the increasing of the function of the skin and bowels.

In cases seen early, these principles of treatment are usually sufficient.

DISCUSSION.

DR. R. B. GILBERT, Louisville, Ky.—This is certainly a very important subject, for the successful management of scarlet fever is a great desideratum. It is well known that many of these cases are not brought to a successful issue. I agree with most of the statements made in the paper. One treatment not referred to was popularized some time ago and advocated by the late Dr. J. Lewis Smith, the idea being that scarlet fever tended directly toward death from the onset, and that, therefore, from the first the treatment should be supporting. He often began the treatment by giving the ammoniocitrate of iron. It has been my own custom to use this remedy in these cases regardless of what other conditions might arise. I believe many cases are benefited by it, and that the method is superior to the plan of waiting until the patient has already become anemic. Mild diuretics are also indicated, though, of course, we should employ no highly stimulating diuretic. Mild carbonated waters should be given in abundance, and by such free elimination we should seek to minimize the danger of nephritis. I am not thoroughly in accord with the use of so many baths. It is difficult to carry out in private practice, and in a few instances in which I have insisted on such baths and the patients have died I have been accused of contributing to their death. A great deal can be done toward the successful management of scarlet fever by inunctions, and I know of nothing better than lard, which is cheap and always at hand. It may possibly be made a little more efficacious by the addition of carbolic acid, although it is chiefly of use in controlling the itching. I have often seen cases of scarlet fever at the beginning of the desquamation in which the temperature of the patient was reduced two degrees by a thorough inunction. Only two years ago I was asked to take charge of a case that had been under the care of an intelligent homeopathic practitioner of my city. His medicines had exerted no controlling effect on the fever, and as exfoliation had already begun and the chief symptoms were the high temperature and the intense itching, I recommended a general inunction with lard. After waiting thirty-five minutes we found that the boy was so comfortable that he was dozing, though sufficiently awake to say to me: "Doctor, please do that again, it makes me feel so good." I do not think there is any need for any heroic treatment of the temperature unless the maximum daily temperature exceeds 102 F. When it does go beyond this point I make use of sodium salicylate made from the natural source.

DR. G. A. HERMANN, Hamilton, O.—I wish to refer to a case in which a boy was doing so well that I discharged him as cured. I was greatly surprised in a few days when the father told me the child was dead. On inquiry I found that the boy had passed very little urine for the last twenty-four hours. Death had evidently resulted from nephritis. In another case in which I neglected the kidneys I had much trouble with the child for two years, trying to restore the general health. Since these experiences I have been most careful to attend to the functional activity of the kidneys.

DR. J. H. HANNA, Covington, Tenn.—I recall the case of a child of about 6 years of age, who fell and bent her arm. I put it in a splint and kept it there for four weeks, after which the arm was straight and apparently in excellent condition. About four weeks later the child fell again and bent the same arm in an opposite direction. The arm could then be straightened just as one would a green stick. It was kept in a splint for three or four weeks. Once more the child fell with the splint, and succeeded this time in bending the arm in the opposite direction again. It seemed to me that in that case there was a deficiency of lime which caused this bending of the bone. There had been some little trouble with the kidneys. After this the arm did well. With regard to inunctions, I think vaselin is one of the best remedies for this purpose, and I am of the opinion that it prevents the spread of the disease by preventing the dissemination of the desquamated epithelium. If carbolic acid is simply stirred into the vaselin to make a 10 per cent. cintment, it will be found that the mixture is very unevenly made, and this may cause serious trouble.

DR. CHARLES G. KERLEY, New York—I support the reader of the paper in everything he has said. I would like to keep my scarlet fever patients in bed at least four weeks. I am also in favor of cold applications when the fever needs attention. Mothers must be taught that there is no danger in such applications in any of the exanthema. The idea that the disease will "strike in" is an old and exploded fallacy. I do not approve of a fountain syringe for nasal irrigation, preferring to use instillations by means of a teaspoon, or some similar method. I am not particularly fond of carbolic acid in oily mixtures for the skin dressings, being rather afraid of absorption. I much prefer some simple inunction, such as vaselin, and think it answers every purpose.

According to my observation, very few cases of scarlet fever die from scarlatina poisoning, but usually through some of the complications. The parts which must be watched particularly are the ears, the heart, kidneys and the lungs. I have seen a few cases of endocarditis develop in connection with scarlet fever. It is very necessary to examine the urine at least every other day.

I am glad attention was called to the fact that there may be a suppurative otitis entirely unassociated with pain. I have been called in consultation not a few times because there was a high temperature which could not be accounted for. On looking into the ear the cause of the fever was found in an otitis which had not made itself known by the presence of pain.

DR. B. R. SHURLY, Detroit—There is one phase of the treatment of scarlet fever to which I desire to refer, i. e., the administration of antistreptococcus serum. I have had but two malignant cases during the past year, which have given me an opportunity to use this serum, and, unfortunately, in both instances the serum was not administered until late in the disease. There was a fatal result in both cases. I should like to hear further reports of the results from this treatment. It seems to me that the key to the whole situation is to be found in the throat; the complications of otitis media, endocarditis and kidney trouble are simply due to absorption from the pathologic state of the nasopharynx. This emphasizes the importance of thorough irrigation of the nose and throat in the various stages of this disease.

DR. E. T. SHELLY, Atchison, Kas.—I wish to inquire with regard to the use of diphtheritic antitoxin in scarlet fever. I think Dr. Holt has recommended that children in institutions suffering from any of the exanthemata and having suspicious throats should be given diphtheria antitoxin.

DR. JOHN M. DODSON, Chicago—With regard to the use of antistreptococcus serum, I should like to say that Dr. Class of Chicago, whom I know to be an earnest and enthusiastic worker, believed a few years ago that there had been discov-

cred in a certain diplococcus the specific cause of scarlet fever. He was at that time connected with the health department of Chicago. At the meeting last year rather positive statements were made with reference to this organism as the causal factor, and it was pronounced to be unquestionably the cause of scarlet fever. I feel very sure that that statement was made on insufficient grounds. In the laboratories of Rush Medical College a very thorough study of the organisms found in the throat and blood of scarlet fever patients has been made during the past year, and it has been determined that the organism I have already referred to is not a specific organism, and can not be identified as a definite micro-organism to accord with the statements made by Dr. Class. At one time it was thought that garden earth was a very necessary culture medium, but it was soon discovered that the organism would grow on a great many media, and that the organism itself was not uniform in its morphologic or cultural characteristics. I may add that streptococci are not always present in scarlet fever, although they are present in the majority of severe cases, and many of the phenomena of scarlet fever are traceable to streptococcus secondary infection. I think it is likely that some other organism not yet discovered, possibly a protozoön, is the cause of scarlet fever. Herein lies the difficulty of using the antistreptococcus serum. Another difficulty is that there is a large number of varieties of streptococci, and each variety requires a serum produced by that particular variety to successfully antagonize it. This seems to be an insuperable obstacle in practice. When streptococcus infection arises we are compelled to use whatever antistreptococcus serum is available, and it is more than probable that it will be from an entirely different variety of streptococcus, and be, consequently, wholly ineffective. The practice in Chicago seems to be to determine, if possible, the nature of the membranous angina before resorting to the use of diphtheria antitoxin. In the majority of cases the sore throat of scarlet fever is not due to the diphtheria bacillus, although this organism is sometimes present.

DR. A. G. PERSON, Snyder, Texas—I have had one case recently which seems to me to clearly sustain the recommendation of the essayist in favor of a milk or liquid diet. The first case in the epidemic occurred in a girl of 15. I recommended that she be kept in bed on a milk diet. She recovered rapidly, and as her appetite improved she insisted on a mixed diet. Her father wrote me, while in New Orleans attending the Polyclinic, that she had a relapse and a very severe kidney complication. Six other children have all passed safely through the disease, as they could be more easily controlled.

DR. ORVILLE A. KENNEDY, Louisville, Ky.—I desire to emphasize the importance of watching all through the course of the disease for complications and of guarding against the spread of the disease. To prevent ear and throat complications keep the nasopharynx thoroughly cleansed. To prevent kidney complications, a liquid diet is most important. To prevent the spread of the disease inunctions are very useful. For this purpose I use, and find it very effective, not only to prevent the spread of the scales, but to allay the itching, a solution of thymol and eucalyptol in olive oil. The patient should be thoroughly anointed with this two or three times a day.

DR. H. M. MCCLANAHAN, Omaha—In the case of scarlatinal nephritis, occurring about the third or fourth week, I question the wisdom of giving any diuretic at that time, as I consider it better to give the kidneys physiologic rest by stimulating the activity of the skin and bowels. As to the use of cool baths, it does seem to me that when we are convinced of the efficacy and virtue of a treatment it is our duty to educate the public as to its importance. A number of years ago I encountered a prejudice against baths and declined to treat certain cases because the parents would not allow me to exercise my own sincere judgment. With regard to inunctions in private practice, I would say that I make use of a mixture made by taking four tablespoonfuls of lard, placing this quantity in a cup and heating it in hot water for half an hour, and then adding a cake of white wax and a teaspoonful of the oil of eucalyptus. This makes an elegant and thoroughly sterile preparation. In my practice it is extremely rare to have a pulmonary complication in case of scarlet fever, and I presume it is more common along the coast. I am glad the fact has been emphasized that an otitis not infrequently develops in scarlet fever without any pain. I think it is the duty of the physician in this disease to examine the ears with a mirror at intervals of two or three days. I do not feel that I can speak with authority on the use of antistreptococcus serum. I have used it on the theory that the complications of scarlet fever are generally due to some variety of streptococcus, and this view has been borne out by the excellent article recently published by Hektoen. I have always understood that the membranous sore throat of scarlet fever is not, as a rule, due to the Kelbs-Loeffler bacillus, and hence it does not seem to me wise to give the antidiphtheritic serum in those cases. Again, I have never yet seen a case of laryngeal stenosis complicating the membranous sore throat of scarlet fever.

TETANUS PROPHYLAXIS AND SUSPECTED WOUNDS.

JOSEPH McFARLAND, M.D.
PHILADELPHIA.

In 1899, in association with E. M. Ranck, I published a paper in the *Journal of Comparative Medicine and Veterinary Archives* entitled "Tetanus Toxin and Antitoxin." In addition to general facts regarding tetanus, the tetanus bacillus and the toxin and antitoxin, there were recorded some practical experiences with the antitoxin as a prophylactic, which, probably because of the nature of the rest of the paper, escaped the attention they deserved.

The observations to which I again call attention were made in one of the large antitoxin factories of this country on a number of horses somewhat exceeding 800, and continuing over a period of nearly four years. These 800 horses were used for immunization experiments in manufacturing different therapeutic serums, and were constantly being injected and bled at frequent intervals, and occasionally suffered from local lesions consequent upon the irritative action of the injected toxins.

At the time the laboratory and stables were in an old building, which, though it was kept very clean and occasionally disinfected, seemed to be badly infected with tetanus. Our first attempts at stamping out the disease were by thoroughly cleansing and disinfecting the stables, and washing the horses with disinfecting solutions, as well as by exercising every precaution to prevent the dissemination of dust.

In spite of these precautions, the death rate from tetanus sometimes rose so high as to make us seriously consider abandoning the quarters, or temporarily suspending business. The highest death rate was in 1898, when it reached 10 per cent., and it was not until we had had this experience that I instituted the regular and systematic immunization with antitetanic serum, as a means of preventing the disease, and every horse was immunized every three months. The periodical treatment consisted of an injection of from 10 to 25 c.c. of a low grade of antitetanic serum, the injection being repeated in about ten days. The effect was immediate and striking, and taking the result by years, we find the following: 1897, no precautions taken to prevent tetanus, death rate 8 per cent.; 1898, no precautions taken until late in the year, and then antitetanic serum used unsystematically and in insufficient doses, death rate 10 per cent.; 1899, systematic immunization of every horse, carried out as described, death rate from tetanus, 1 per cent.; 1900, systematic immunization of every horse continued, death rate less than 1 per cent.

These observations show the thoroughly reliable result to be obtained by the proper and systematic employment

of antitetanic serum as a prophylactic. Such employment does not apply to antitoxin factories only, but has a far-reaching application in all departments of human and veterinary medicine. We averaged 200 horses a year in the stables mentioned. In two years the deaths from tetanus numbered 36, in the next two years about 4. We, therefore, saved the lives of 32 horses by this prophylactic treatment.

Every day there apply for treatment in the dispensaries of our large cities patients suffering from lacerated and punctured wounds of the hands and feet that are suspicious in character, and concerning which one is in doubt whether tetanus may not develop. In spite of the ordinary antiseptic treatment, in many of these cases tetanus does develop, and many of the patients die.

Those familiar with the treatment of tetanus by any of the methods yet suggested (including that with antitoxin) are quite familiar with the fact that after tetanus once develops, the probability of curing the patient is very slight.

The practical conclusion that must be drawn from the observations on the antitoxin horses seems to me inevitable; that in all suspicious wounds, that is, all wounds at all likely to be followed by tetanus, the antitoxin should be administered as a prophylactic. This I have urged repeatedly in other writings, and have taught my pupils from year to year, but there are objections that have some slight weight. The antitetanic serum is expensive, does not keep indefinitely, and must be administered by subcutaneous injection, which alarms and pains the patient. In many cases, therefore, dispensaries and practicing physicians are unable to provide and employ the serum, a matter of economy and penury which undoubtedly costs life.

I was very much interested during December, 1902, by a description given me by Dr. Damaso Rivas, who, returning from the laboratory of Professor Calmette at Lille, related to me some experiments that he had seen conducted there, and in which he had participated, which showed that antitetanic serum, while not absorbed from the skin or mucous membranes, is readily absorbed by denuded surfaces, and when the dry serum is dusted on wounds it is readily absorbed, and confers immunity on animals. I at once recognized the practical importance of this observation, and conducted a series of experiments to show how useful dry antitetanic serum as a dusting powder might be. It did not take many experiments to prove the correctness of Professor Calmette's observation.

Experiment 1.—Sixteen adult guinea-pigs were employed. The abdomen of each was shaved, and with a sharp scalpel the skin was cross-hatched, as in performing the operation of vaccination, and an area of about 1 cm. in diameter was abraded. With a platinum loop a drop of a pure culture of the tetanus bacillus was thoroughly rubbed into the abraded surface, and in one-half of the animals the seat of operation was dressed with cotton saturated with collodium; in the other half the abraded surface was thickly sprinkled with pulverized antitetanic serum, and then similarly dressed with collodium. The results were striking. Every animal of the first series died with typical tetanic convulsions, while every one of the second series lived and showed no symptoms.

In order to compare the effects of mixed infection, I performed the following experiment:

Experiment 2.—Eight adult guinea-pigs were prepared by shaving the abdomen and cross-hatching the surface, as described. Each was now infected with a suspension of garden earth, which was rubbed into the injured surface. In four cases the surface was dressed with collodium; in the remaining four, thickly sprinkled with the antitetanic powder and then dressed with cotton and the collodium. These animals all recovered, there evidently being no tetanus bacilli in the garden earth employed.

It then occurred to me that if an active but harmless antiseptic could be combined with the antitetanic powder the powder might be doubly useful; first, in preventing tetanus; second, in inhibiting the growth of other micro-organisms. As best adapted for this purpose, I selected chloretone, which is both analgesic and antiseptic, and performed the following experiment:

Experiment 3.—Eight guinea-pigs prepared as already described were infected with pure cultures of the tetanus bacillus. In four the wound was simply dressed with cotton and collodium; in the remaining four, thickly sprinkled with the dusting powder, consisting of antitetanic powder and chloretone, then covered with cotton and collodium. The unprotected animals died in two days with typical tetanic convulsions. Of the remaining animals, one died on the sixth day of tetanus.

This showed that the combination of equal parts of chloretone and antitetanic powder had too greatly diluted the antitetanic powder, and made it less useful than when the purer dried serum was used. It was suggested that chloretone, which is cheaper, might suffice, and that if wounds were dusted with it, an antitetanic serum would be unnecessary. So another series of experiments was undertaken.

Experiment 4.—Eight guinea-pigs were employed, all prepared and infected with the tetanus cultures, as usual, and in one-half the wound was thickly sprinkled with chloretone, then dressed with cotton and collodium. All of these animals died of tetanus.

I was loath to publish the results of these experiments until I had learned what Professor Calmette intended to do with the observations he had already made, and accordingly corresponded with him, telling him of my experiments, and of the important bearing I thought they had upon the prophylactic treatment of possibly infected wounds. He answered that within a day or two from the time he wrote me, he was expecting shortly to make a communication on the subject, and a later mail brought me a pamphlet containing his communication made to the Academy of Science at Paris, May 11, 1903, in which his own and Dr. Rivas' experiments are given, and in which the results of the experiments performed in his laboratory and in my laboratory are shown to be uniform.

The advantages of this method of treatment are many. The dry antitetanic serum preserves its activity indefinitely. It requires no instrumental administration, etc., but can be conveniently sprinkled, from the bottle in which it is dispensed, on the wound after the surface has been thoroughly cleansed and prepared to receive it. It is devoid of irritating properties, slowly dissolves and is absorbed, and when thus applied has the double advantage of neutralizing the toxin of the tetanus bacillus as it is elaborated in the wound, and of being absorbed into the patient's blood, where it remains to neutralize any toxin subsequently formed and absorbed.

I feel that these experiments of Professor Calmette and myself should have a most important bearing on dispensary practice, and that particularly in those districts of our country where tetanus is known to be frequent, the powder should be systematically employed for dressing of wounds, and in lieu of the observations to which attention is directed in the opening of this communication, I would recommend a very wide application of the antitetanic serum for prophylaxis against tetanus in both human and veterinary practice.

SPRING WATER AND TYPHOID FEVER.

The firmly rooted popular belief in the superior excellence of ground water, and especially of spring water, is not difficult to understand. The usual clearness and brilliancy of such waters, together with their coolness, render them highly attractive to the eye and pleasing to the taste. In times of typhoid epidemics "pure spring water" is a shibboleth of undoubted commercial value. A strong and wholly natural preference for ground water as a source of town supply has been evinced on many occasions. The citizens of Ithaca, after becoming fully aware of the origin of the late typhoid epidemic, could not express too deeply their abhorrence of surface water. In France for many years *les eaux des sources* have held the highest position in the estimation of most municipal authorities, and in that country spring waters have been widely accepted as the most desirable source of municipal supply.

The last decade, however, has seen a profound change in the position accorded by sanitarians to spring waters. From many quarters evidence has accumulated that the delectable appearance of spring water too often masks a treacherous nature. Gärtner,[1] in a recent monograph on this subject, has brought together a formidable array of outbreaks of typhoid fever attributed with greater or less certainty to spring water. He clearly shows that in many instances the trusted spring water is nothing but unfiltered surface water of dubious antecedents. In chalk and limestone regions especially, where the existence of extensive subterranean channels and crevices renders it exceedingly difficult to determine the sources from which a spring is fed, the danger of surface contamination is ever present. The calamitous typhoid epidemic at Worthing, England, in 1893, will at once occur to the student of epidemiology as a case where the fissures in chalk were responsible for an unusually extensive outbreak of disease. In some regions small brooks or rivers which are known to receive sewage pollution may disappear wholly or in part in openings in their beds, only to emerge at a remote point as gushing and copious "springs" which confiding inhabitants will make use of for drinking purposes with a calm assurance of safety which would indeed be ludicrous if it did not so often lead to appalling consequences. The changeable character of spring water, both as regards turbidity and bacterial content, its dependence upon the amount of rainfall, upon the topography of the country and the underlying geological strata, and above all, the often insuperable difficulty of learning the real origin of the water, are not features that increase its desirability as a source of supply. Gärtner points out that geologists are largely responsible for the growth of the modern views regarding the uncertain character of spring water, and quotes with unqualified approval a statement by the geologist, Heim, that he would drink the filtered water of Lake Zurich with a feeling of greater security than the water from the majority of springs with which he was acquainted. "Springs are changeable; to-day good, tomorrow, perhaps, unsafe."

If a widespread reaction has already set in against the indiscriminate use of ground waters it is amply justified. There have been several noteworthy illustrations of the unsafe character of spring water in the hygienic annals of recent years. The water supply of Paris, which is perhaps the most extensive modern system of municipal spring water supply, was for a time highly vaunted as an example of a naturally pure water, as compared with the "merely purified" water of Berlin and other European capitals. Pure spring water was eloquently contrasted with filtered surface water; innocence was said to be better than repentance. It was not long after its introduction, however, before the Paris supply fell under a cloud. The epidemics of typhoid fever in 1894 and 1899, and the searching investigations to which they gave rise, have shown unmistakably that the spring water from the region of the Vanne is not only not beyond suspicion, but that it is actually responsible for an excessive amount of typhoid fever in Paris. The facts brought to light by these and similar inquiries have caused a decided change in the opinion of French sanitarians regarding the character of spring water, and recent utterances by Brouardel and others indicate that in France spring water has had its day as the ideal for a supply.

In addition to the epidemiologic evidence, recent bacteriologic investigation has also cast doubt on the universally wholesome character of waters of this class. Horton[2] has reported finding the colon bacillus in water from a number of springs and driven wells, and concludes as the result of his investigations that the fact that water is derived from a drilled well can in no wise be taken as a guarantee of its potability.

We can no longer hesitate to admit the fact that many spring and ground waters are nothing but insufficiently filtered surface waters which may, indeed, have traversed long distances underground, but which have met in their course no layer of soil or sand of purifying power. To continue to place implicit trust in waters of this sort is to tempt further "accidents" of a kind with which medical literature already teems.

FAT BABIES AND HEALTH.

In a recent issue an English contemporary[1] calls attention to the mischief which is being done by the present standard that is accepted as regards healthy babies. As this paper well says, at baby shows the prize is practically always given to the fattest baby. There is a tradition current among mothers, as far as the memory of man runneth, that fat babies are just the pink of perfection. The surest index of this is that all manufacturers of artificial infant foods advertise their wondrous virtues by photographs of thoroughly rounded, and at times positively obese dumplings of babies. Mothers are very proud of their young hopefuls if they are a mass of curves and dimples with deep folds at all the joints and cushions of fat that conceal their anatomy so effectively as to make them formless little masses of humanity. They have been encouraged in this idea by the mistake of some of the classic painters who have pictured babies of this kind as if they were models of all that is finest in babyhood.

Fatness is said to be a distinctive quality of superlative beauty in the harems of the East, but there is no need to appeal to the antifat-cure crowded advertising columns of our magazines to prove that this standard is not generally accepted among the occidentals. Fatness is no more truly beautiful in a baby than in an adult. Opposed to the traditions that fat babies are healthy is the generally accepted medical opinion that, on the contrary, very fat infants are especially prone to succumb to certain diseases. Very few physicians dare to give a good prognosis when their child patient is very fat. This is not surprising since the blanket of fat in which all the child's organs are wrapped absorbs all the heat manufactured during the course of a fever, and makes antipyretic measures very difficult of application. Besides, the presence of fat seems of itself to be a distinct hindrance to the exercise of organic function with consequent lowering of vital resistance. Whether fat babies are more liable to infection than others is not definitely decided, but it is well known that they are at least as prone to the minor infections, such as colds, and to the so-called ordinary diseases of childhood, as are much thinner babies.

It seems worth while to call attention to this subject just at this time because it is during the warm weather that fat babies are distinctly at a physical disadvantage. They swelter and chafe, and, as can readily be understood, are much more uncomfortable than are their thin fellows of the same age. They lose sleep easily, and are thus predisposed to nervous complications in any serious illness. Yet all the winter months before the dreaded second summer fond, anxious mothers have been mainly engaged in securing the accumulation of as much fat as possible on baby under the mistaken notion that this means good health.

There is no doubt that some of the responsibility for the persistence of the erroneous idea of the correlation of fat and health in infants must accrue to physicians who have either encouraged or at least have not properly opposed the notion. As the *Lancet* says, "Fat babies to the touch are cold, gelatinous and flabby, with none of the elasticity and tone characteristic of the vigorous, healthy, breast-fed baby. When fed a large proportion of carbohydrates of sugar, infants are apt to have a curiously translucent, almost opalescent appearance of the tissues." This represents the true state of the fat baby which is rather a pathologic specimen than the model of health they are considered to be by the judges at the baby shows. There is no doubt that if this idea could be properly brought before the public many infants would be healthier and more resistant to infection than is the case at the present time, when deliberate "feeding for fat" is almost the rule, though such infants are rather seriously handicapped than helped by the additional weight they have to carry in the race of life.

1. Lancet, June 20, 1903.

A LAW AGAINST "NASTY ADVERTISEMENTS" IN MICHIGAN.

The new Michigan Medical Practice Act, which goes into force in a short time,[1] had added to it just before its final passage an amendment which authorized the Board of Registration in Medicine to revoke the certificate, after due notice and hearing, of any registered practitioner who inserts advertisements in newspapers, pamphlets, circulars or other written or printed paper relative to venereal disease or other matter of an obscene or offensive nature derogatory to good morals. This amendment was unanimously passed by the legislature, and with practically no opposition; not even from the newspapers. The profession in Michigan has become well organized, and was thus able to take up this work with reasonable hope of success. It was this effort of a united profession, backed by one or two newspapers, which made success possible. Due credit should be especially given to one newspaper, the *Detroit Journal*, which for a long time has refused to admit to its pages any quack advertisements, and which fought for and was one of the factors in securing the amendment.

It is to be regretted that this work can not at once be carried further, and that these nasty, as well as demoralizing, advertisements can not be entirely eliminated from our newspapers everywhere. The Michigan law only reaches the advertising quacks in Michigan, and does not affect the same class who reside in other states and yet who may advertise in the Michigan newspapers. If the legislators in other states will enact similar laws and give the licensing boards the right to revoke certificates for such advertising—and such legislation can be had in every state if the profession will go about it in the right way—then we may hope to purge our profession of its greatest curse, and remove from newspapers the filthy and disgraceful advertisements, not only in Michigan, but elsewhere. The law is a most righteous one, no matter from what point of view we may look at

1. See page 45.

it, and Michigan has certainly set an example for other states to follow. This is not of interest to the medical profession alone, but much more in the interest of the public and good morals generally. In fact, it is in the interest of preventive medicine. The result of the wretched stuff sent out by these advertising quacks is not only debasing, but is also the means of making many who read it hypochondriacal, and has a direct tendency to the increase of mental disease. It is the policy of this class of advertisers to demoralize, as well as to frighten, their victims, and then to rob them. The corrupting influence of such advertisements is manifest to everyone, but their mentally weakening and depressing influence is best evidenced before the practicing physician. It is time that our legislators should be called to a sense of their responsibilities in this matter.

We earnestly urge those who are interested in legislation everywhere to consider the advisability and possibility of getting such an amendment to the now existing Medical Practice Acts, as that to which we have above referred, and to make it to apply not only to those who advertise within the state, but also to those who advertise in papers beyond its limits.

FOURTH OF JULY INJURIES.

As long as we celebrate the Fourth of July in the customary manner, we may expect the usual number of injuries on this day. This is one of the cases in which we can do little in the way of preventive medicine, yet while we may not hope to reduce the number of accidents, by proper care we may be able to minimize the ill effects which so frequently follow them.

The injuries common to Fourth of July accidents may be divided into two classes: (1) Those which produce considerable damage to the person, but are attended with little danger to life; (2) those which are comparatively trivial, so far as the damage done is concerned, but which are attended with great danger to life. In the first class may be placed such injuries as the loss of a portion or all of a hand or arm, due, for instance, to the explosion of a giant cracker. In these cases, although the loss of tissue may be great, the end is usually in recovery. They should all be treated as infected wounds from the start, and great conservatism should be exercised in the removal of injured parts.

It is to the second class to which attention is particularly directed. To this class belong the numerous small wounds produced by the toy pistol, the blank cartridge, the fulminate cap, etc. These wounds often appear trivial and unimportant on the surface, but herein lies one of their chief dangers. They appear so trivial that frequently they are neglected. Their principal characteristic is the penetration of the soft parts by a small particle of foreign matter, such as the wad, particles of unburned powder, a portion of a cap, etc. These foreign bodies carry into the depths of the wound the ordinary pyogenic germs or the much more dangerous tetanus bacillus, and unless the wound receives the proper treatment from the start, the most disastrous results may follow.

The tetanus bacillus finds around a foreign body in the depth of a small penetrating wound from which the air is excluded, the best possible conditions for its development and growth. Such being the case, the plan of treatment is well defined. No matter how innocent or trivial these wounds may appear on the surface, they should invariably be laid open freely at the earliest possible moment, either under local or general anesthesia, in order that it may be thoroughly done; all foreign matter sought and removed; the wound cleansed with an antiseptic solution—1-1,000 bichlorid or dilute peroxid, and dressed as an open wound to which the air has free access.

If this line of treatment be instituted early, there will be little danger of tetanus. In case the wound is not seen until some days after its reception, the same open method of treatment should be instituted, but in addition, it is advisable to inject tetanus antitoxin as a prophylactic. By following this simple plan, many of the deaths due to lock-jaw after apparently slight Fourth of July injuries will be prevented.

ACCIDENTAL INFECTION WITH BLASTOMYCOSIS.

The clinical report in THE JOURNAL last week[1] of a remarkably interesting and important case of accidental infection with blastomycosis (more properly oïdiomycosis) by Dr. Newton Evans, calls for a word or two of further comment.

It will be recalled that the infection followed an insignificant wound received at an autopsy of the case of systemic blastomycosis reported by Ormsby and Miller and discussed at that time briefly in the editorial[2] columns of THE JOURNAL. The clinical cause and the gross appearances of the case of accidental inoculation are well described in Dr. Evans' paper. The special feature of the case to which it seems well to direct attention is the fact that this is the first known instance of blastomycetic infection in which the exact source of the disease is established. That source undoubtedly being another case of blastomycosis, we have here the nearest approach as yet at hand to establish definitely upon unassailable basis the pathogenic importance of the blastomycetic organisms concerned, or mold-fungi, and which appear to be identical in the two cases. It has not yet been possible to produce experimentally in animals any process at all similar to blastomycetic dermatitis in man, and consequently more or less doubt has been expressed on various sides, principally by clinicians, as to there really being any disease like blastomycetic dermatitis. This is evident enough from the discussion of Dr. Evans' paper.

In Germany the so-called "American disease" has been ridiculed freely, especially by Kromayer, and this in spite of the fact that the clinical course of the disease

1. Journal A. M. A., June 27, 1903, p. 1772.
2. Journal A. M. A., May 23, 1903, p. 1444.

and the gross appearances of the lesions are quite distinctive and characteristic, while at the same time the histology of the lesions is peculiar and distinctly different from that of cutaneous carcinoma, tuberculosis and syphilis. The history of blastomycetic dermatitis shows that attention was first called to its occurrence in Chicago by pathologists whose interest was arrested primarily by the distinctive histologic peculiarities of the lesions. Now the situation of the organisms in the cutaneous lesions, often away from the surface, and their relations to the well-known miliary abscesses, speak strongly against accidental presence, while the absence of tubercle bacilli, as shown best by negative results from inoculation of guinea-pigs, serves to exclude definitely at least tuberculosis. And then the development of generalized blastomycosis with massive accumulations of blastomycetes in the lungs and elsewhere demonstrates further their pathogenic importance, as well as the eventual seriousness of the disease.

Finally, we have Evans' case of undoubted accidental inoculation to still further clinch the matter. The fact that the disease in this case described by Evans seems to be localized in the skin, while the source of the infection was a general blastomycosis, resembling greatly the so-called protozoic disease of Posadas, Wernicke, Rixford and Gilchrist, would go to strengthen the claim advanced by Ricketts[3] that the "protozoic disease" is a manifestation of the same infectious process as blastomycetic dermatitis.

AN ENDOWMENT FOR MEDICAL EDUCATION.

Some months ago we announced a professional gift to the medical department of the University of Chicago—Rush Medical College—by Mr. Rockefeller. Representations had been made to Rockefeller of the needs of the institution if it is to carry out the ideals in medical education that its friends desired, the necessary amount being put at $7,000,000 to $10,000,000. Mr. Rockefeller then made his offer to give the required amount provided $1,000,000 was raised by Chicago. July 1, 1903, was set as the date at which the money should be raised. On Tuesday the committee having the matter in charge unofficially represented that the million dollars had been raised. Few realize what this means to medical education of the United States. It is of national interest, for it means a long step forward, and one that will affect the medical education of the United States. It is not Chicago only, but the whole country that will profit; it is not the medical department of the University of Chicago alone, but all medical educational institutions that will feel the impetus and be benefited.

SOIL NITRIFICATION AND MOSQUITOES.

The extinction of malaria is one of the great medical questions of the day, and it is only natural that active minds should constantly find new points bearing on this subject. One of the latest suggestions is that given by Dr. Arthur R. Waddell in the *Lancet*, June 6. In experiments on the destruction of mosquitoes and mosquito larvæ he was impressed with the observation that very minute quantities of ammonia were decidedly fatal to these insects. Using strong liquor ammonia as a standard, a solution of 1 in 4,000 proved absolutely fatal for mature larvæ, and a solution so much weaker killed immature larvæ that he made the calculation that 1 in 20,000 or 30,000 would be sufficient to make water uninhabitable for them. His experiments indicated that ammonia is poisonous to mature larvæ in all its combinations. This suggested to him the fact that the nitrification of the soil might be one of the active factors in the prevention of malaria through its unfavorable effects on the growth of mosquitoes, and he thought that he saw evidence of this in the decrease of malaria under more scientific cultivation in certain parts of Great Britain. He attributes this to the enormously increased use of nitrogenous manures and the cultivation of plants whose roots give support to nitrifying bacteria, such as clover, etc. Against this, though he does not mention it, might be stated the fact that virgin soil is particularly favorable to malaria, though its nitrogen content has not been exhausted by cultivation, and that malaria in this country decreases with cultivation, even without a very extensive addition of nitrogen fertilizers. Still, there may be something in the author's suggestion, and at least it is worthy of consideration.

A HOUSE ENDEMIC OF MALARIA.

An interesting example of the mosquito origin of malaria is furnished by a house endemic reported by Jancsó.[1] It seems to explain how fresh cases may occasionally spring up in winter, aside from the well-recognized relapses. In November and December, with ice and snow on the ground, there occurred in the hospital, both among the patients and the staff of assistants, nine cases of malaria, recognized as such by the clinical behavior and by the detection in the blood of the parasites, in every case those of the estivo-autumnal variety. The explanation of this occurrence, unusual for the time and place, was found in the fact that a few days before the cage containing several specimens of anopheles that had been experimentally infected with this variety of plasmodium was overturned accidentally, the mosquitoes escaping, but not, as was thought at first, being destroyed by the cold. As was later discovered, the insects had sought out wards and rooms that, while not as warm as the incubator temperature they had left, still enabled them to live, and to bite several patients ill of diseases other than malaria, as well as several well individuals, among whom was Dr. Jancsó himself. The culprits were found, and several were examined, showing the sporozoites that had developed from the previous experimental feeding. Dates, clinical features, microscopic findings in the blood and in the mosquitoes are all carefully given, so that the proof seems conclusive that the origin of this house epidemic certainly lay in the bites of the twenty escaped and infected anopheles. This outbreak of malaria in winter, at a time when mosquitoes are supposed to be dead or hibernating, is, therefore, no argument against the mosquito theory, as some would

3. Journal of Medical Research, 1902, vi, No. 3.

1. Jancsó: Deutches Archiv für Klinische Medicin, Bd. lxxvi, p. 474.

be inclined to contend at first thought, but a convincing proof as to the rôle of the mosquito in the transmission of the disease. It teaches a lesson, too, as to the great care that should be exercised in experimental work with these insects, particularly when they are infected with the more dangerous estivo-autumnal parasites. One of the nine victims in this endemic was a sufferer from typhoid, and a second succumbed to pneumonia. Secondary or mixed infection with malaria is a serious matter.

Medical News.

ILLINOIS.

Chicago.

Smallpox.—Only two new cases of smallpox were received in the Isolation Hospital during the week ended June 20. One child, 28 days old, died in the hospital, fifteen were discharged recovered and eighteen remained under treatment at the close of the week.

Low Mortality.—The remarkably low mortality rate of the month continued during the week ended June 27. The 454 deaths reported represent an annual rate of 12.54 per 1,000. For the twenty-seven days of the month the rate has been 12.70, as compared with 13.12 for June, 1902, and with an average of 14.12 for the ten Junes of 1893-1902 inclusive.

Personal.—Dr. Rachelle Yarros has gone to Europe for a year of study.——Dr. William L. Ballenger has been elected to the chair of otology, rhinology and laryngology, made vacant by the resignation of Dr. Moreau R. Brown.——Dr. Frank Allport has been elected clinical professor of ophthalmology in the Northwestern University Medical School.

Exercises at Rush.—On June 17, 180 students, including 6 women, received degrees at the convocation of Rush Medical College. Dr. Simon Flexner, Philadelphia, made the doctorate address on "An Era of Medical Discovery." Dr. Frank Billings, dean of the faculty, announced that the major portion of the $1,000,000 required to secure the $8,000,000 required for hospital and advanced clinical work had already been secured.

Englewood Hospital Incorporated.—A new corporation has been organized, known as the Englewood Hospital and Training School. This will succeed the Englewood Union Hospital, which will surrender its charter. The new institution is not for pecuniary profit. The plan contemplates the purchase of land for $20,000, on which will be erected a hospital building to cost $80,000, and to accommodate 148 patients, and this building will be equipped at a cost of $20,000.

MARYLAND.

Personal—Dr. Lawrence C. Freeny, Pittsville, Wicomico County, has been elected resident physician and superintendent of the Peninsular Hospital, Salisbury.

Sanitarium for Liquor and Drug Habitues.—Dr. Edwin Geer of Baltimore has purchased 68 acres for $30,000 in Green Spring Valley, Baltimore County, and will build thereon a sanitarium for the treatment of persons addicted to liquor and drug habits. It will be called the Cecil Heights Sanitarium and will accommodate 23 patients. The consulting staff consists of Drs. H. M. Hurd, T. A. Ashby, C. G. Hill, J. D. Blake, Geo. J. Preston, John W. Chambers and Thos. S. Latimer, Baltimore.

Selects Site for Naval Hospital.—Surgeon-General Rixey, U. S. Navy, visited Annapolis last week to select a site for the naval hospital to be erected in the Academy grounds. The highest point in the grounds was chosen. A building several stories in height, with accommodations for about 100 persons, and to cost from $100,000 to $150,000, is contemplated. The "open-air" plan will be followed, and the wards will be separated so as to secure abundant light and ventilation. Wards for officers and men will be in different parts of the building.

Baltimore.

Operating Rooms Opened.—The new operating rooms of St. Agnes' Hospital were opened with formal ceremonies and a banquet June 25.

Adopts Standard Classification.—Health Commissioner Bosley, in order to preserve uniformity, has adopted the system of mortality statistics in use by the U. S. Census Office and approved by the American Public Health Association.

University Appointments.—At the University of Maryland Dr. John R. Winslow has been made clinical professor of diseases of throat and nose, Dr. R. H. Johnston demonstrator in the department, and Dr. Hubert Richardson demonstrator of physiologic chemistry.

Lowered Death Rate.—The cool weather kept down the death rate last week. The deaths numbered only 135, 26 being from consumption and 9 from pneumonia. The death rate per 1,000 was 12.50, the usual proportion of 1 to 2 between whites and colored being observed.

Echoes from the Crim Sale.—The medical books belonging to the Crim collection of antiques, etc., were sold last week, and with them the entire collection has been disposed of. The entire receipts amount to about $80,000. The 400 charts belonging to the late Professor Robey and used by him in his anatomic lectures brought only $32. The Bourgery anatomy, eight volumes folio, brought only $24. As previously stated, the University of Maryland Medical School ultimately received the great bulk of the estate. Dr. Crim's house brought only $100 at public sale, but it was much out of repair, and there was a large ground rent on it.

Personal.—Among those who sailed from this port to Bremen on June 27 were Drs. Henry L. Hilgartner, A. Crawford, W. A. Jack, Anna Johnston, and M. P. Tilley.——Dr. A. Kerr Bond has gone to England, where he will spend a month in the Manchester Children's Hospital.——Dr. T. P. McCormick will spend July at Groton, Conn.——Drs. Thomas McCrae and W. G. McCallum sailed for Europe June 27.——Dr. B. B. Lanier will spend the summer at the White Sulphur Springs, Va., and Dr. John A. Luetscher at Ocean City, Md.——Dr. A. H. Whitridge is in London.—Dr. John Turner is in London.——Or. C. C. Bombaugh will spend the summer at Newport.——Dr. L. McLane Tiffany sailed for Bremen on June 16.——Dr. J. J. Abell has received the degree of A. M. from the University of Michigan.

MASSACHUSETTS.

Boston.

Resignations Demanded.—Because of disobedience to rules, the resignations of the three senior surgical house officers of the Massachusetts General Hospital were demanded by the trustees and received by them. The trouble originated in a disturbance in the house officers' quarters, for which the seniors were held responsible.

The City's Health and Mortality.—Two weeks of rain have given Boston a death rate of 12.71 per 1,000 for the two weeks ending June 27, or a total of 283 deaths. Of this number 57 were under one year old and 85 under 5 years old. Pneumonia caused 26 deaths; heart disease, 26; bronchitis, 5, and marasmus, 5. There were reported 80 cases of diphtheria with three deaths; 55 of scarlet fever, with 1 death; 50 of typhoid fever, with 3 deaths; 103 of measles, with 4 deaths, and 29 of tuberculosis, with 32 deaths.

Floating Hospital in Commission.—The Boston Floating Hospital opens again for patients on Tuesday next. Dr. Robert W. Hastings will again serve as resident physician, and will be assisted by Drs. Milton G. Sturgis, John F. Fennessy, and Nathaniel L. Berry. Two junior house officers and six medical assistants, all advanced medical students, complete the house staff. Drs. Samuel Brick, Frederick Coggeshall and Arthur W. Fairbanks are the visiting physicians for this season. Arthur I. Kendall is to serve as the Fellow of the Rockefeller Institute for Medical Research, working to determine the relation of the Shiga bacillus to the cases of ileocolitis in the vicinity of Boston. No marked changes have been made in the hospital boat, but the various departments have been perfected for the best use of space in the very limited quarters.

NEW YORK.

A Gift from Rockefeller.—A gift of $25,000 has been received from John D. Rockefeller toward the fund of $60,000 being raised for a central building for the Stony Wold Sanitarium at Lake Rushaqua, New York.

Health Officer Dismissed.—At a meeting of the Rochester Common Council the recommendation of the public safety committee which has been investigating the recent smallpox epidemic in the city that Health Officer George W. Goler be dismissed, was adopted by the council.

Dr. Didama an Octogenarian.—On June 17, Dr. Henry D. Didama, Syracuse, dean of the medical profession of

Onondaga County; dean of the faculty of Syracuse Medical College; a member and once vice-president of the American Medical Association; some-time president of the New York State Medical Association, celebrated his eightieth birthday anniversary. Numbers of his friends called on the venerable physician, bearing congratulations and gifts. Save for his abundant white hair there was little in Dr. Didama's appearance to indicate the advanced age which he had attained. He entertained his guests with reminiscences of his early experiences when, fifty-two years ago, he entered on the practice of medicine.

Syracuse College Commencement.—On June 10, a class of 29 received diplomas and had the Hippocratic oath, as modified by Dr. Didama, administered by the adapter, at the commencement exercises of the Syracuse College of Medicine. The text of the oath is as follows:

JUSJURANDUM.

You, and each of you, do solemnly promise that, according to your ability and judgment, you will keep this obligation and stipulation.

That you will follow that regimen which, according to your best judgment, you consider to be for the benefit of your patients and abstain from whatever is injurious. That you will give no deadly medicine to anyone if asked, nor suggest any such counsel. That, with purity and holiness, you will pass your life and practice your art. That into whatever houses you enter you will go for the advantage of the sick, and will abstain from every act of mischief and corruption. That whatever, in connection with your professional practice, or not in connection with it, you may see or hear, you will not divulge, holding that all such things should be kept secret.

Do you so promise?

While you continue to keep this promise inviolate, may it be granted to you to enjoy life and the practice of your art, respected always by all men; but should you break through and violate this obligation, may the reverse be your lot.

Improvement in Care of Insane.—The New York State Commission of Lunacy has inaugurated a number of measures of improvement in the care of the insane during the past few months, including the reorganization of the Pathologic Institute where more than 60 medical men connected with the hospitals have been instructed during the past winter in clinical pathologic and physiologic psychiatric work. A system of medical interneship has been inaugurated in the hospital and nearly 30 have entered during the present year. Through the efforts of the commission, the legislature has recently passed an act appointing a medical inspector to the insane with 39 institutions under charge, which has never been inaugurated before, especially in the case of private asylums. Certain conditions and changes are projected, such as the foundation of a hospital on the colony system, the attachment of a tuberculosis hospital to three of the existing state institutions, the enlargement of the working colony, the inauguration of summer camps, the building of nurses' homes, officers' residences, etc. A bill providing for emergency commitments, as recommended by the Lunacy Commission, was passed by the legislature at its last session, which it is thought will be of great benefit, especially as regards urgent cases which were heretofore sent to jails and station houses. The food supply has been improved, and through the efforts of New York State, the federal government has passed a law making a limit of three years instead of one for deportation of alien insane, that is to say, immigrants becoming insane within three years after landing may be sent back to the country from which they came. The movement for the establishment of a reception hospital for acute curable cases in large cities has gained strength, and while the bill for a psychopathic hospital in New York City failed to pass, the attempt will be renewed with the next legislature, and it is hoped with success.

Buffalo.

Pure Water Investigation.—The Board of Aldermen has voted an appropriation of $2,000 for experts to investigate the requirements of a pure water supply for Buffalo.

Personal.—Dr. Roswell Park is ill with erysipelas.——Dr. Harvey R. Gaylord of the New York State Cancer Laboratory has recovered from his recent illness and has sailed for Europe.——Dr. Burt C. Johnson has returned from Europe.——Dr. Max Keiser will spend the summer in Vienna.——Dr. A. L. Benedict sailed for a six weeks' visit to Europe.

May Health.—The monthly health report for May shows an annual death rate of 15.69 per 1,000. The principal causes of death were as follows: Consumption, 39; diphtheria, 6; typhoid fever, 8; debility, 36; cancer, 14; apoplexy, 16; meningitis, 23; endocarditis, 10; valvular disease of the heart, 26; pneumonia, 48; appendicitis, 8; nephritis, 26; and violence, 40. Total deaths for May, 497, as compared to 422 for May, 1902.

Protest Against Goodsell-Bedel Bill.—At the regular quarterly meeting of the Erie County Medical Association, held June 8, 1903, Dr. A. A. Jones presiding, the following resolutions, presented by the committee on public health and charities, Dr. Julius Ullman, chairman, were unanimously adopted:

WHEREAS, There has recently been passed by the legislature of the State of New York an act to amend the public health law in relation to the establishment of public sanatoria, hospitals or camps for the treatment of tuberculosis; which act reads: "A hospital, camp or other establishment for the treatment of patients suffering from the disease known as pulmonary tuberculosis shall not be established in any town, by any person, association, corporation or municipality unless the board of supervisors of the county and the town board of the town shall each adopt a resolution authorizing the establishment thereof and describing the limits of the locality in which the same may be established.

WHEREAS, This bill, known as the Goodsell-Bedel bill, which has become effective by the signature of his excellency, the governor, makes it impossible for any city in the state, fraternal order or individual to establish such an institution except under conditions which are practically prohibitive; and

WHEREAS, Such sanatoria, hospitals and camps for consumptives, properly conducted, have proven most valuable in the treatment of tuberculosis, greatly decreasing the mortality rate and, by the observation of hygienic laws, have prevented the spread of the disease; and

WHEREAS, The location of such sanatoria actually relatively decreased the mortality from this disease in villages where so located as compared to other villages of like inhabitants; and

WHEREAS, There are in the State of New York many consumptive poor who are in urgent need of such sanatoria treatment; and

WHEREAS, This law, as enacted, is detrimental to the lives of thousands of citizens of this state now suffering from tuberculosis; and

WHEREAS, The spread of this disease, especially in crowded cities, will be augmented, thus making it an act of great injustice and inhumanity; therefore

Resolved, That the Erie County Medical Association urgently petition the legislature of the State of New York for its immediate repeal; and

Resolved, That copies of these resolutions be sent to his excellency, Governor Odell, the executive officers of the state and the senators and assemblymen representing this district at Albany.

New York City.

Cornell Commencement.—The fifth annual commencement of Cornell Medical College was held in New York, June 3.

Dog Muzzling Ordinance Passed.—Despite considerable opposition the board of aldermen, in response to a demand from the New York County Medical Association and from others familiar with what such legislation has accomplished in the way of controlling hydrophobia, has enacted the following ordinance:

Hereafter it shall be unlawful to permit any dog to go abroad at large in any of the streets, highways or public places in the City of New York unless such dog shall be securely muzzled so that it be impossible for it to bite, tear or otherwise wound with the teeth any human being or other animal.

Alleged Antitoxin Frauds.—As a result of the prosecution of a number of physicians for alleged procuring of antitoxin for sale under the pretense of distributing it without cost to indigent people, considerable indignation has been aroused among members of the profession, and this has found expression in resolutions of protest adopted by the East Side Physicians' Club, which are in part as follows:

Resolved, That the physicians of the East Side, in mass meeting assembled, deplore the circumstances and emphatically protest against the unmerited and summary procedure of the department of health, a procedure which demoralizes the community, offends the profession, and gravely injures the accused physicians and their families by branding them as common criminals.

So far, the defense has been that the physicians only charged a proper fee for the administration of the antitoxin, and did not charge for the antitoxin itself.

PENNSYLVANIA.

Gift to Hospital.—On May 14, the twenty-fifth anniversary of their wedding day, Mr. and Mrs. Horace Brock of Lebanon signified to the board of managers of the Good Samaritan Hospital their intention to present to the institution a home for nurses.

State Board Examinations.—From June 16 to 19, inclusive, the State Boards of Medical Examiners held simultaneously sessions in Pittsburg and Philadelphia. There were 391 applicants for license before the regular board. Announcements of results of the examinations will be sent to the applicants on July 31.

Legacy to University of Pennsylvania.—By the will of the late Dr. Spencer Morris, Mount Morris, a university graduate of 1871, the university is made his residuary legatee. The interest of the sum bequeathed, amounting to about $400, will be given each year to the student who shall pass the best examination for the degree of Doctor of Medicine.

Crusade Against Impure Foods.—The Dairy and Food Bureau, through its commissioner, continues its crusade against impure

foodstuffs. Retail dealers have recently been put under bail to answer in court to the charge of selling impure lard, cocoa and vinegar. There is a rumor that dealers will test the constitutionality of the law creating the Dairy and Food Commissioner.

Philadelphia.

Bathhouses Open for Season.—The thirteen public bathhouses of the city were opened for the season June 15. During the first week they were patronized by 122,086 persons.

Voodoo Doctor Guilty.—George P. Hossey, the negro herb doctor, charged with furnishing the wife of William G. Danz arsenic for the poisoning of the latter on June 26, was pronounced by the jury guilty of murder in the first degree.

Enforce Anti-Spitting Ordinance.—The superintendent of police has recently ordered police lieutenants strictly to enforce the ordinance of March 9, 1903, imposing a fine of $1 and costs for each offense of spitting on sidewalks, in public conveyances or places of public resort.

Physician Gets Fraction of Fee.—Dr. Walter C. Browning, it will be remembered, presented a claim of $350,000 for professional services against the estate of the late State Senator Chris L. Magee. The court's decision recently rendered in Pittsburg allows Dr. Browning $34,163.

Typhoid on the Wane.—Typhoid fever, which for months has been almost epidemic, has shown a marked decrease in the past few weeks. For the week ended June 20, 147 new cases were reported, as against 238 for the previous week. For the same period 37 new cases of smallpox were reported.

The Late Dr. Thomas G. Morton.—The faculty of the Philadelphia Polyclinic and College for Graduates in Medicine has recorded by resolutions its sense of deep loss in the death of Dr. Thomas George Morton, one of the founders of the institution and throughout the period of its existence successively professor and emeritus professor of orthopedic surgery.

University Commencement.—At the one hundred and forty-seventh commencement of the University of Pennsylvania, June 17, a class of 107 graduated in medicine. Honorary degrees were conferred on seven distinguished men. One of the latter was Colonel William Crawford Gorgas, U. S. Army, to whose sanitary administration at Havana is due in large measure the comparative immunity of that city from yellow fever and other contagious diseases. The degree of Doctor of Science was fittingly bestowed on Colonel Gorgas.

Strauss Gives Pasteurizing Plant.—In accordance with the plans of Dr. Edward Martin, director of the Department of Health and Charities, a central plant to provide at cost pasteurized and modified milk for infants is being established on Filbert, near 15th street. The proposed plant will prepare 10,000 gallons of milk daily. Private subscriptions will defray the expense of preparation. The plant is said to be the gift of Mr. Strauss of New York, and the Children's Aid Society will have charge of the distribution of the milk. Milk will probably be provided free of charge where parents are too poor to pay. A census of infants under one year is being taken by the police to determine where distributing stations are most needed. Four additional milk inspectors have been appointed, and it is the purpose rigidly to enforce the laws against the selling of impure or adulterated milk. Shops will be closed and fines imposed where fraud is detected.

Pollution of the Schuylkill.—The recent inspection of the Schuylkill River by Dr. A. C. Abbott, chief of the bureau of health, and a corps of assistants, in order to determine sources of pollution, has led to the conclusion that the water supply of Philadelphia could not be worse, and that its quality has not improved in the last five years, since the agitation for purity began. Filth of all description is thrown into the river, and as much of the pollution is outside the city limits, if any practical good is to come from the inspection, it must be by cooperation of the State Board of Health. The latter body will be asked to unite with the city officials in using all lawful means to prevent contamination of the river. Upper Roxborough's filter plant was placed in operation on June 26. It will finally filter about 18,000,000 gallons a day. It is at present limited to 8,000,000 gallons a day to allow the beds to ripen. To stop pollution of the Schuylkill, steps have been taken by the department of health to abate 76 nuisances in Manayunk. Chief Abbott has had printed and distributed to every householder "boil water" cards. The cards are provided with hangers, and are to be hung on water faucets. The notices read: "Important to householders.—Water containing typhoid germs is rendered harmless by boiling one minute. Boil water in the evening. Keep it in a clean, cool place over night. Keep free from dust."

GENERAL.

Colleges Combine.—The consolidation of the Saginaw Valley Medical College, Saginaw, with the Michigan College of Medicine and Surgery, Detroit, was consummated, June 29.

The Health of Cuba.—The monthly report of Dr. Carlos J. Finlay, chief sanitary officer for the Island of Cuba, says the showing for 1902 and the beginning of 1903 is very satisfactory, not only in regard to the complete exemption from yellow fever and smallpox, but also in the number of deaths from malaria and in the total mortality. There has been no smallpox on the island since July, 1900, nor yellow fever since September, 1901.

Frauds on Physicians.—A correspondent in Wisconsin has requested THE JOURNAL to warn its readers against two firms whose silvery-tongued solicitors have made him and many of his professional brethren yield their signatures and their money. The first is a "Medical Exchange," in which physicians are invited to buy stock, thereby securing the privilege of purchasing surgical instruments and supplies at considerably below market price. The exchange, it seems, is migratory, and is believed by some of its stockholders to be a fraud, as they have been unable to get money, goods or satisfaction from the concern. The second firm is a so-called "Art Publishing Company" of Chicago, which, he avers, has furnished him with engravings from worn-out plates, and thus far has failed to keep the promise implied in its contract of furnishing him in addition, free of charge, a premium ranging from a set of dishes or stem-winding watch (metal not being defined) to a musical instrument.

CANADA.

High Infant Mortality.—The Montreal health department has announced that one-half of the deaths in that city last week were of infants. The normal weekly death rate is about 115, but the total deaths last week amounted to 186, of which number 93 were children. It is considered that this high death rate is due to the inferior quality of the water supply.

No Federation of Universities in Maritime Provinces.—The alumni of King's College, Windsor, N. S., held an important meeting June 17, at which 300 members were admitted to the Alumni Association. The proposal to consolidate with Dalhousie University was warmly discussed and voted down. It is proposed to reorganize King's College, to reconstruct the faculty and to have a new dean.

Amalgamation of Trinity and Toronto Medical Colleges.—Progress has been made in this matter to the extent that the corporations of the two medical faculties have agreed to amalgamation. It now depends for final consummation on the action of the corporation of Trinity University whether they will accept federation with the University of Toronto. The meeting for this purpose will be held in the early part of July.

Vaccination By-Law Illegal.—Judgment has been rendered by Mr. Recorder Weir of Montreal declaring the vaccination by-law illegal in so far as it tends to prevent an employer from allowing his employes to enter any office or factory without holding a certificate of vaccination. Action had been taken by the city against a life assurance company for allowing an employe to frequent the office without the necessary certificate of vaccination.

Personals.—Dr. A. E. Garrow, Montreal, has returned home after three months spent in German hospitals.——Dr. R. Ernest McConnell of Volksrust, Transvaal, is visiting his father, Dr. J. B. McConnell of Montreal.——The following Toronto physicians have gone to England for the summer: Drs. F. LeM. Grasett, R. A. Reeve, Alexander McPhedran, D. King Smith, and Mr. Irving H. Cameron.——Dr. Arthur Jukes Johnson has been appointed chief coroner for the city of Toronto.

FOREIGN.

Mortality of European Capital Cities.—London's mortality for 1902 was at the rate of 18.64 per 1,000; that of Paris, 18.4; of Vienna, 19.4, and of St. Petersburg, 23.

Memorial Meeting in Honor of Gerhardt.—The late Prof. Carl Gerhardt of Berlin would have been 70 years old if he had lived to May 5. On that date a memorial ceremony was held at the Berlin Charité, addressed by Professor Martius of Rostock. A portrait of Gerhardt was presented by his assistants, to be placed in the medical clinic formerly under his charge.

New University Buildings at Berne.—The installation of the Berne University in its new quarters was duly celebrated June 4. The buildings have cost about a quarter of a million dollars, and on the campus a statue of Alb. von Haller is to be erected.

The Divided Twin Dying.—The young Hindoo, Radica, is slowly succumbing to the disease which caused the death of her twin sister from whom she was separated a year or two ago. She is confined to her bed and has been admitted to the "Cancer Home" at Paris as an incurable.

Study of Malaria in Russia.—The Russian National Medical Association, which honored the memory of Pirogoff by changing its name to that of the "Pirogoff Association of Russian Physicians," has equipped and sent out two expeditions for the study of malaria, one in the Caucasus and the other in the Woronesh province. The latter is in charge of the privat docent of bacteriology at Moscow, Dr. Berestnew.

Adulterated Milk.—A writer in the *Journal des Debats* attributes the high and increasing infant mortality of Paris and the provinces to the use of watered milk and the failure of the authorities properly to inspect the milk supply to hospitals. In Hanover, otherwise a healthy city, the infant mortality is said to be 60 per cent. higher than that of Washington, D. C., where strict inspection of milk is maintained.

Foreign Medical Students in France.—There are only four medical students from the United States inscribed in the French medical colleges at present. The number has not been above six since 1896 and 1897, when it was respectively 14 and 10. The more stringent regulations since then have reduced the total number of foreign students from about 1,054 to 585. The total number of French medical students has also diminished from 7,779 to 6,960.

Convalescent Home for Physicians in Germany.—The appeal for funds to erect a resort for convalescent members of the profession in Germany has been mentioned in these columns. It has already met with a response, as the director of the stock company exploiting the baths at Salzschlirf has donated a beautiful tract of land for the purpose at Ilbeshausen, Hess. Hills, dales and virgin forest combine to render it an ideal spot. A committee is to be appointed to solicit subscriptions and the project will probably soon be realized.

A Paris Physician Condemned for Larceny.—The *Journal de Méd. de Paris* gives the particulars of a case which has been pending in the courts for two years. A physician was accused of stealing some statuettes, an umbrella and some cosmetics at a large department store. He confessed that he took the goods to pawn them to get food to eat. He stated that he had only a single patient and that the latter was ill only at long intervals. The case was appealed, but the decision of the lower court was confirmed, condemning the physician to six months' imprisonment.

Medals for Victims of Professional Duty.—The Paris authorities have bestowed medals on seven nurses in the hospitals who during the past year have contracted a contagious disease from some patient in their care. The medal is awarded to "victims of professional duty." A pension is given the family of persons who have died "victims of professional devotion," referring to some exceptional act of self-sacrifice. This pension was recently awarded to the family of a young French physician in Algiers who himself proceeded to disinfect the premises where plague had occurred when no one else would approach the place.

The New Cancer Research Institute at Berlin.—In order to provide better facilities for von Leyden's research on cancer in connection with his medical clinic, the Berlin University authorities have erected a laboratory and two wards in the grounds of the Charité Hospital, near Koch's barracks, for this purpose. Each ward has eight beds with two private rooms. The institution was formally inaugurated June 8. Dr. F. Blumenthal has charge of the work, assisted by F. Meyer, L. Michaelis and the chemist Wolf. Loewenthal and Braunstein are voluntary assistants.

French Committee on Public Hygiene at St. Louis.—Professor Brouardel of Paris is president of the committee and Boix of the *Archives Gén. de Méd.* is secretary, with Ledé and Manson as assistants. The vice-presidents are E. Besnier, L. Labbé and Leroy des Barres. Bordas and A. Josias have been appointed to deliver addresses. All are prominent and well-known scientific workers. Josias' address on serotherapy of typhoid fever was one of the most interesting communications at the Madrid Congress. Labbé has been recently elected a member of the Institut, and his friends collected subscriptions to present him with a medal as a souvenir of the occasion. Brouardel's fame is international as a leader in hygiene and forensic medicine.

Measures Against Dispensary Abuse at Paris.—Lermoyez states that at the Saint-Antoine clinic of laryngology, etc., in his charge all applicants suspected of being capable of paying are given some soothing prescription and told to return in a week, urgent cases excepted. Their names and addresses are taken as usual, but are written on a pink slip as "suspects," and the pink slips are sent to the office, where they are given to the persons connected with the investigating force of the "medical aid at home" service. In due time the pink slips return marked "treatment refused" or "granted," as may be. These measures have been found necessary by the authorities in the various hospitals as the placards warning that the service is restricted to the poor have proved insufficient to check this abuse. Lermoyez's article in the last *Presse Medicale* is a very amusing sketch of the subject, describing his surprise when his attention was called one day to the fact that his charity service seemed to be becoming a gathering point for society people. He condemns in strong terms the practice which seems to be widespread at Paris for practitioners to send to this free service some of their pet, well-to-do clients with a letter commending them to the special attention of the physicians in charge. The dispensary abuse injures the poor, the tax-payers, and above all, the members of the profession. It is like making the man who is to be hung send out and buy the rope. He relates some curious examples of the abuse, and refutes the arguments that might be raised against the present plan, among others the plea that putting the patient off for a week might conflict with his leaving town if he lived in the country: "Why should the tax-payers of Paris pay for dilating the urethral strictures or curetting the adenoid vegetations of people who reside at the other end of France?"

Death Rate of British Towns.—Merthyr Tydvil, according to the registrar-general's report for 1902, is the deadliest town in Great Britain. It has an infant mortality of 185 per 1,000; it led all towns for death by violence, and was near the unenviable top as regards smallpox, fever and diarrhea. In order of decreasing deadliness come Liverpool, Wigan, Manchester, Middlesborough, Burnley, Hanley, Bootle, St. Helens, Newcastle-on-Tyne, Oldham, Preston, South Shields, Rhondda, Stockport, Sunderland and Birmingham. The healthiest of 76 great towns is Hornsey, where the death rate is only 9.80 per 1,000. This is much better than the whole of England and Wales, whose death rate is 16.28, and better even than the smaller towns and rural districts, whose rate is 14.80. Other most healthy great towns are Walthamstow, Leyton, East Ham, Willesden and Croydon; and the healthiest seaside towns of size are Bournemouth (13.05), Hastings (13.91), Yarmouth (15.50), and Brighton (15.59). London's rate is 18.64, which is well above the average, and places the metropolis forty-eighth on the list. The worst towns for measles were Burnley, Bristol, Barrow and Cardiff, and for scarlet fever West Bromwich, Burnley, Bolton, St. Helens and Wigan. Diphtheria was worst in Hanley, Rhondda and Middlesborough, and whooping cough in South Shields and Barrow. In London itself the healthiest suburbs are Hampstead (10.8—a shade below Hornsey), Stoke Newington (13.4), Wandsworth (13.5), Lewisham (13.6), Paddington (14.6). The worst places to live in are Finsbury, Southwark, Holborn, Bermondsey, Bethnal-green, Shoreditch, Stepney and the city. The year was a healthy one for London, and disease was much below the average, excepting smallpox, cancer, suicide and homicide. There were 329 deaths from horses and vehicles, 3,410 from other violence, 535 suicides, 71 homicides and 7 executions.

Correspondence.

The Transmission of Yellow Fever.

A REPLY TO DR. AGRAMONTE.

WASHINGTON, D. C., June 26, 1903.

To the Editor:—In connection with my paper published in THE JOURNAL of May 23 several statements made by my esteemed colleague, Dr. Aristides Agramonte, in his letter published in the JOURNAL of June 13, call for reply, and I beg to be permitted to submit the following necessary explanations: With manifest feeling Dr. Agramonte takes exception to the omission of his name in the early part of my paper—and natur-

ally too, in view of his lack of knowledge of the facts—and proceeds to show that I was in error in my statement that the decision to put the mosquito theory to a practical test was arrived at during a consultation between Drs. Reed, Lazear and myself. He then makes certain statements in regard to our late colleague, Dr. Lazear, with which, with one exception, I heartily agree, and which no one, so far as I know, has ever, openly or tacitly, attempted to deny or conceal. I am then accused of being an unbeliever at the time when I was bitten, and the letter closes with an arraignment of me for attempting to deprive Finlay of the "glory of his discovery," and an emphatic assertion of Finlay's right of priority.

In the first place Dr. Agramonte's name was omitted because he was not present at the meeting referred to, which took place at Columbia Barracks, where we were quartered, on the eve of Dr. Reed's departure for the United States in the beginning of August, 1900. As Dr. Agramonte resided in Havana and had a separate laboratory at Military Hospital No. 1, he was absent from many similar consultations. It is true, however, as he states, that he was present at a previous meeting, when the mosquito theory was brought up, and it is also true that the various theories and probabilities were the subjects of constant consideration and discussion. At the meeting in question Carter's observations pointing to a period of incubation or development in an intermediate host were brought up, so also was the erratic manner in which the disease seemed to jump from house to house, often across a street or farther, without intercommunication between the inhabitants, in other words the transmission of the disease through the atmosphere; the numerous points of resemblance between the modes of dissemination and seasonal occurrence of yellow fever and malaria, etc. These were not new topics, for they had been discussed almost daily, and a decision was promptly arrived at to put the mosquito theory to a practical test, and if that failed of result, to resort to anaërobic cultivations, particularly from the intestine. The serious nature of the work decided on and the risk entailed on it were fully considered, and we all agreed, as the best justification we could offer for experimentation on others, to submit to the same risk of inoculation ourselves. The fact of the meeting, the conclusions arrived at and the agreement to submit ourselves to the bites of contaminated mosquitoes are susceptible of proof, for they were stated by me in a letter written a few months later to the widow of our devoted colleague (Dr. Lazear) in response to her request for a detailed statement of the circumstances attendant on her husband's death.

I acknowledge frankly that I was, in a measure, an unbeliever at the time I submitted to inoculation, for the evidence Finlay presented was far from convincing, chiefly because he had worked in a hotbed of the disease. I was perfectly willing, however, to take a soldier's chances, and afterward enjoyed the satisfaction of being the first person to become aware, by actual proof, of the efficacy of the mosquito, and the first genuine case of experimental yellow fever on record. These facts are also susceptible of proof. There was strong ground for the assumption on the part of certain persons that I did not believe in the mosquito theory, even after I suffered my attack. During my convalescence I was plied with questions by Doctors Finlay, Guiteras, Agramonte and others who inquired whether the mosquito had anything to do with my attack. My replies were always evasive and intended to mislead, because of the necessity for the strictest secrecy to avoid premature publicity. I made only one exception in a medical officer of the regular army, now in Washington, whom I knew to be an intimate and trusted friend of Major Reed. As a matter of fact the results were not communicated to Dr. Agramonte until Dr. Reed was about to leave the island a second time, with the completed report to be read at the meeting of the American Public Health Association at Indianapolis in October, 1900. He then told me he was about to carry the paper into Havana and acquaint him with its contents; on his return he manifested much amusement over Dr. Agramonte's astonishment when the news was imparted to him.

Lastly, perhaps, it is natural that the Cuban ex-member of our board should desire to see Dr. Finlay awarded credit for the discovery, but Dr. Finlay is no more entitled to credit for the discovery of the mosquito theory of the transmission of yellow fever than Manson is for the discovery of a similar theory for malarial fever. The cases are precisely analogous, except that Finlay attempted to prove his hypothesis and failed; Manson did not enjoy the opportunity, and he gives full credit to Ross. According to the article cited by Agramonte (*Medical Record*, New York, May 27, 1899), Dr. Finlay is also entitled to credit for another discovery, viz.: that malarial infection is transmitted by flies from the bloody dejecta of patients, through the intermediation of food and beverages. Finlay here makes the statement that "Koch's assertion that 'where there are no mosquitoes there is no malaria,' is altogether too absolute."

Those who are interested in the subject of yellow fever are referred to the statements of Dr. George H. F. Nuttall of the University of Cambridge, in No. 2, Vol. III, of the *Journal of Hygiene*, which has just been brought to my notice.

JAMES CARROLL, M.D.

Pension and Accident Acts in New Zealand.

HUNTLY, N. Z.

To the Editor:—We have in this country much legislation which is somewhat experimental in type and nearly always socialistic in form. This is certainly very much of a haven for the laboring man. He has his old age pension, etc. There is one law which may prove of interest: "The Accident Compensation Act." An employer is responsible for all accidents occurring to his employes. The employer insures his men in an accident insurance company. The coal mine in this town pays over $1,150 per annum as a premium. I will give some cases showing the effect of the act.

I was called to the local coal mine to see a man who had fallen in the mine, causing an incised wound about 3 in. long over the spine and in the lumbar region. There was no apparent injury to the spine or cord. He was under my care for three weeks; the wound healed perfectly. The man was permitted to go to Auckland for a change. While there he apparently became worse and then returned to us with a diagnosis of traumatic neurasthenia. The accident compensation act gave the man half the daily wage he received before the accident. He also received aid from the local miners' accident society. The total amount received per week was more than he previously earned while at work. The company which carried the insurance for the mine sent an agent, who bought off the miner. The latter soon recovered and manifested enough energy to immediately walk four miles.

Another miner, while lifting, received a hernia, went to the local hospital and was operated on. He has received aid for the past four months.

I may say that an employer uses great care in selecting his men. One man with defective hearing, who was in the employ of the mine several years, was discharged when the act came into effect. He can now only secure employment on contract.

The friendly societies are now much of a disturbing element to the medical men of Auckland. They have decreased their fee of £1 ($4.85) per annum to 15 shillings ($3.60). The British Medical Association Branch in New Zealand opposed this and threatened to ostracize any who might accept the societies on such fees. The societies then established their own dispensary and called for four men, each to receive $1,940 per annum and act for the societies only. Three men were secured who will have under their care about 2,000 souls. The societies recently brought their grievance before the premier. He partially made a promise to place some new clause in the Arbitration and Conciliation Act, a board of which settles all disputes between the employer and the employe.

Recently the *Gracchus* from England via Africa brought smallpox to one of our many ports. This has brought to prominence a law not in the past closely adhered to. All children must be vaccinated within four months after registration of birth, unless the parents forward a statement that they are conscientiously opposed to vaccination. Public vaccinators are appointed for each district, and all vaccine is furnished by the public health department.

P. M. KELLER.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

EHRLICH'S TRIPLE STAIN.

ROUND LAKE, MINN., June 20, 1903.

To the Editor:—Please publish in your next issue of THE JOURNAL Ehrlich's "triple stain" for blood and technic.

HENRY WIEDOW.

ANS.—It is given in von Jaksch's Clinical Diagnosis as follows: "Ehrlich's Triacid Mixture.—This consists of 115 c.c. of a saturated watery solution of orange-green; 125 c.c. of a saturated watery solution of acid fuchsin to which 20 per cent. alcohol has been added. To this are added 125 c.c. of a saturated watery solution of methyl-green and 77 c.c. absolute alcohol, the mixture being well shaken the while."

State Boards of Registration.

The New Michigan Law.

The amended Michigan law provides for a board of registration, five from the regular school, two each from the homeopathic and eclectic and one from the physio-medical school of practice. The governor may select such appointees from the latest lists furnished by the respective state societies of the said schools; such lists to contain at least treble the number of names that each society has members on the board. In case of failure to furnish such lists he may appoint according to his own judgment. All such appointees shall be legally registered physicians and graduates in good standing of reputable medical colleges and actively engaged in the practice of medicine for at least six years immediately preceding the time of appointment.

SECTION 3.—On and after the date of the passage of this act, all men and women who wish to begin the practice of medicine and surgery in any of its branches in this state, shall make application to the State Board of Registration in Medicine, to be registered and for a certificate of registration. This registration and certificate shall be granted to such applicants as shall give satisfactory proofs of being 21 years of age and of good moral character, but only on compliance with at least one of the following conditions contained in subdivisions one, two and three of this section:

First. The applicant shall be registered and given a certificate of registration if he shall satisfactorily pass an examination before the board on the following subjects: Anatomy, physiology, chemistry, pathology, materia medica and therapeutics, toxicology, histology, practice of medicine, surgery, obstetrics, gynecology, mental and nervous diseases, diseases of the eye, ear, nose and throat, bacteriology, hygiene, public health laws of Michigan and medical jurisprudence; said examination to be conducted as follows:

(*a*) The applicant shall pay a fee of $25.00 prior to examination. Provided, that the examination fee for graduates of any medical school in the State of Michigan, approved by said board, shall be the sum of $10.00.

(*b*) The examination shall be in writing, oral, or both.

(*c*) The questions on all subjects, except in materia medica and therapeutics and practice of medicine, shall be such as may be answered alike by all schools of medicine.

(*d*) The applicant shall, if possible, be examined in materia medica and therapeutics and practice of medicine by those members of the board, or by a qualified examiner appointed by the board, belonging to the same school as the applicant, and no applicant shall be rejected because of his adherence to any particular system of practice.

(*e*) An average percentage of at least 75 per cent. of correct answers shall be required from every candidate. No additional fee shall be charged by this board for the registration of those who successfully pass such examination. Provided, however, that such applicant for examination shall have a diploma from a legally incorporated, regularly established and reputable college of medicine within the states, territories, districts and provinces of the United States, or within any foreign nation (provided such foreign nation accord a like privilege to graduates of approved medical colleges of this state) having at least a four years' course of seven months in each calendar year, as shall be approved and designated by the board of registration in medicine. Also provided that such applicant shall have, previous to the beginning of his course in medicine, a diploma from a recognized and reputable high school, academy, college or university, having a classical course, or shall pass an examination equivalent at least to the minimum standard of preliminary education adopted and published by the board before examiners appointed by and in accordance with the regulations of aforesaid board, and at such time and place as the board may designate. Provided, a student entering a college in Michigan having a preliminary examination of a standard approval by the board of registration in medicine shall not be required to take this examination. Provided, that this requirement of preliminary education shall not apply to those students who, on the date of the passage of this act, were regularly registered as students of legally organized and reputable medical colleges approved of by said board. And provided, also, that the requirement of medical education shall not apply to those graduates of legally organized and reputable medical colleges approved of by said board who had graduated from such colleges previous to the date of the passage of this act, and students complying with the other provisions of this section who on January 1st of the present year were regularly registered as students of legally organized and reputable medical colleges of this state, approved of by said board, may obtain a certificate of registration as graduates of such colleges and without examination by the board on payment of a fee of $10.00. The board of registration in medicine shall, from time to time, adopt and publish a minimum standard of medical education, and no medical college shall be approved and designated by said board under this subdivision one, of section three, unless, in the judgment of the board, it conforms with such standard.

Second. The applicant shall be registered and given a certificate of registration if he shall present a certified copy or certificate of registration or license which has been issued to said applicant in any foreign nation where the requirements of registration shall be deemed by said board of registration in medicine to be equivalent to those of this act. Provided, such country shall accord a like privilege to holders of certificates from this board. The fee for registration from applicants of this class shall be $25.00.

Third. The applicant shall be registered and given a certificate of registration if he shall present a certified copy of certificate of registration or license which has been issued to said applicant within the states, territories, districts or provinces of the United States where the requirements for registration shall be deemed by the board of registration in medicine to be equivalent to those of this act, and shall otherwise conform to the rules and regulations agreed on between the state board of which he is a licentiate and said board relative to the recognition and exchange of certificates between states. Provided, such states shall accord a like privilege to holders of certificates from this board. The fee for registration from applicants of this class shall be $25.00.

Fourth. If any person shall unlawfully obtain and procure himself to be registered under this section, either by false and untrue statements contained in his application to the board of registration in medicine, or by presenting to said board a false or untrue diploma or license, or one fraudulently obtained, he shall be deemed guilty of a felony and, on conviction thereof, shall be punished by a fine of not less than $300.00 nor more than $500.00, or imprisonment at hard labor for not less than one year, nor more than three years, or both, at the discretion of the court, and shall forfeit all rights and privileges obtained or conferred on him by virtue of such registration as a physician or surgeon.

Fifth. Any person who shall swear falsely in any affidavit or oral testimony made or given by virtue of the provisions of this act, or the regulations of the board of registration in medicine, shall be deemed guilty of perjury and, on conviction thereof, shall be subject to all the pains and penalties of perjury.

Sixth. The board of registration in medicine shall refuse to issue a certificate of registration provided for in this section to any person guilty of grossly unprofessional and dishonest conduct of a character likely to deceive the public, and said board shall, after due notice and hearing, revoke a certificate issued subsequent to the date of the passage of this act, or subsequent to the date of the passage of Act No. 237 of the Public Acts of 1899, for like cause or for offenses involving moral turpitude, habitual intemperance, the drug habit, or for fraud or perjury in connection with obtaining of a certificate of registration or for a certificate obtained or issued through error, when such offenses shall have been legally established in a court of competent jurisdiction. And, provided further, after the passage of this act, the board may, at its discretion, revoke the certificate of registration, after due notice and hearing, of any registered practitioner who inserts any advertisement in any newspaper, pamphlet, circular, or other written or printed paper, relative to venereal diseases or other matter of any obscene or offensive nature derogatory to good morals.

SEC. 7.—Any person who shall practice medicine or surgery in this state without first complying with the provisions of this act, or any person who shall violate its provisions (except as heretofore provided in Section 3 of this act) shall be deemed guilty of a misdemeanor and, on conviction thereof, shall be punished by a fine of not more than $100.00, or by imprisonment in the county jail for a period of not more than ninety days, or by both such fine and imprisonment, for each offense. It shall be the duty of the prosecuting attorneys of the counties of this state to prosecute violations of the provisions of this act.

Marriages.

R. B. USSERY, M.D., to Miss Buyde Allen, both of Shiloh, Tenn., May 21.

JOHN OSCAR ELROD, M.D., to Miss Eyleen Roberts, both of Forsyth, Ga., June 10.

ROWLAND H. HARRIS, M.D., to Elizabeth M. E. Kerr, at Battle Creek, Mich., June 18.

S. LEO OREN, M.D., Lewistown, Ill., to Miss Helen A. Wise of Davis, Ill., June 11.

DON ALVADOR BARNHART, M.D., to Miss Susie Hammett, both of Huntsville, Mo., June 10.

GREEN EWING HILL, M.D., Girard, Ill., to Miss Hattie N. Miner of McVey, Ill., June 10.

MINOR H. DAY, M.D., Donora, Pa., to Miss L. Jean Mechling of West Sunbury, Pa., June 3.

ELMER D. GARDNER, M.D., Hancock, Mich., to Miss Lulu Skinner of Flint, Mich., June 30.

GEORGE T. MEACHAM, M.D., to Miss Carrie Reed, both of Taylorville, Ill., at Vandalia, June 9.

JAMES ARTHUR VAN HORNE, M.D., Chicago, to Miss Lutie Huntoon of Waterford, Mich., June 10.

ERNEST M. FREEMAN, M.D. Long Beach, Cal., to Mrs. Jessie E. Zavitz of Westminster, Cal., June 3.

FRANK KENWORTHY, M.D., to Miss Eleanor Selene Seebick, both of East End, Pittsburg, Pa., June 17.

RICHARD W. MCCRACKEN, M.D., Union Grove, Wis., to Miss Anna B. Wetmore of Beloit, Wis., June 17.

WALTER N. CHINN, M.D., Hague, Westmoreland County, Va., to Miss Emily Baskerville of Dinwiddie County, Va., June 25.

Deaths.

Isaac Newton Love, M.D.

The many friends of Dr. I. N. Love were shocked to hear of his sudden death, for he was supposed to be in excellent health. Isaac Newton Love was born in Barry, Ill., Sept. 13, 1848, and was, consequently, nearly 55 years of age at the time of his death. At the age of 13 he went to St. Louis to live in the family of his uncle, Dr. J. T. Hodgen, the famous surgeon. After a high-school course he entered the St. Louis Medical College, and was graduated from that institution in 1872. He served as an interne in the St. Louis City Hospital for two years, and then became assistant to Dr. Hodgen. He devoted his attention chiefly to diseases of children, and built up a large practice. For a time he was city physician of St. Louis, and was also instructor in physiology in the college from which he graduated. In 1887 he was elected president of the Mississippi

ISAAC NEWTON LOVE, M.D.

Valley Medical Association, and in the same year was made secretary of the Pediatric Section of the Ninth International Medical Congress. In 1889 he was appointed professor of pediatrics in the St. Louis College of Physicians and Surgeons. He was elected a trustee of the American Medical Association in 1889, and was three times re-elected, serving continuously as a trustee until 1901. In 1893 he was elected vice-president of the American Medical Association, and in 1889 he presided over the Section of Diseases of Children. He founded the *Medical Mirror* in 1890, which he conducted up to the time of his death. He was professor of diseases of children in the Marion-Sims College of Medicine of St. Louis, preceding his removal to New York.

Three years ago he left St. Louis and located in New York City, where he established himself, and was prepared, as he said, to do the best work of his life. In the short time he was there he succeeded beyond expectations in building up a large practice, and his life gave promise of a practice and a social position equal to that which he once enjoyed in St. Louis. On May 29 he went abroad with a patient who had been operated on by Dr. W. T. Bull, and after seeing her comfortably located in Paris, he returned, sailing on the *Aurania*. He appeared remarkably well and happy, and was exceedingly popular on shipboard. He frequently expressed himself as feeling ten years younger, and manifested his good feelings and high spirits in his customary exuberant way. He was chosen by the passengers to present to the captain and officers of the steamer, resolutions of commendation and thanks, and on June 18, while the steamer was in New York Harbor and nearing her pier, he had risen to perform this pleasant task, had read the resolutions and was delivering the presentation speech in his usual happy and felicitous manner when he suddenly clapped his hand to his head, fell to the deck and died in his cabin a few minutes later. The cause of his death was probably rupture of a blood vessel of the brain. He leaves a widow and two children, Delphine and Hodgen, the latter being about 18 years of age.

Dr. Love probably had as large a personal acquaintance among the members of the medical profession in America as any one physician. He was a man of remarkable social qualities and personal attractiveness, and this made him a most agreeable and genial companion. As one of his old associated says of him, he was fond of his friends, faithful to them, and remarkably free from all petty personal or professional jealousies. He was optimistic in his nature, and generally saw the silver lining of passing clouds. He had a genial and friendly disposition. On the day of his death the Editor of THE JOURNAL received a congratulatory letter written by Dr. Love, while in England, in which he spoke enthusiastically of his trip and of his prospects in New York.

The funeral services were held June 22, at St. Paul's Methodist Episcopal Church, New York. The body will eventually be interred in St. Louis.

Orpheus Everts, M.D.

In the death of Dr. Orpheus Everts, at his home in College Hill, Cincinnati, June 19, the profession has lost a man of most attractive personality, a physician of broad attainments and power, and an alienist of more than national repute. Orpheus Everts was born Dec. 18, 1826, in Salem Settlement, Union County, Indiana. He studied medicine under the direction of his father, Dr. Sylvanus Everts, and was graduated from the Indiana Medical College, La Porte, in 1846. At the opening of the Civil War he went to the front as major-surgeon of the 20th Indiana Volunteer Infantry, in which position he remained throughout the war. At the close of the war he devoted his attention especially to diseases of the nervous system; in 1866 he was appointed superintendent of the Indiana Hospital for the Insane at Indianapolis, and filled this position for eleven years. He was also professor of nervous and mental diseases in the Medical College of Indiana. He became well known as an alienist, and had a large consultation practice. He was frequently called on to testify in important medicolegal cases, notable the trial of Guiteau for the assassination of President Garfield.

Since 1880 he has been made superintendent of the Cincinnati Sanitarium. He had been a member of the American Medical Association for a number of years, and was a member of the Ohio State Medical Association and of the Cincinnati Academy of Medicine. One of the last acts of his professional life was to prepare a paper for the Section on Nervous and Mental Diseases of the American Medical Association, for the New Orleans meeting. This paper will appear in THE JOURNAL at an early date.

He had been ill for some weeks. He is survived by a widow, a son—Dr. C. C. Everts of Indianapolis—and two daughters.

John W. F. Moore, M.D. Jefferson Medical College, Philadelphia, 1894, a member of the American Medical Association, Pennsylvania State Medical Society, and some time president and treasurer of the Butler County Medical Society. He was accidentally killed, June 13, by a fall into an unguarded areaway between two buildings. A fracture of the skull at the base of the brain was sustained, and although he lived twelve hours he never regained consciousness. He was 35 years old.

Henry Melville Chase, M.D. Dartmouth Medical College, Hanover, N. H., 1863, formerly an assistant surgeon in the United States Navy, and since 1866 a resident of Lawrence, Mass., died suddenly at his home in that city, June 15, from heart disease, aged 65. He was a member of the Massachusetts Medical Society and of the Lawrence Medical Club, and for several years served Lawrence as a city physician.

Charles F. Deetken, M.D. Long Island College Hospital, Brooklyn, N. Y., 1874, one of the oldest practitioners of Council Bluffs, Iowa, died suddenly at his home in that city, June 19, from heart disease, aged 61. The Council Bluffs Medical

Society, at a special meeting held June 20, adopted resolutions in memory of Dr. Deetken.

Arthur E. McBride, M.D. Louisville Medical College, 1883, died at his home in Sterling, Ill., June 12, from tuberculosis, after an illness of two years, aged 42. He was a member of the Illinois State Medical Society, the North Central Illinois Medical Society, and was retiring president of the Whiteside County Medical Society.

Edward W. Parker, M.D. Medical College of Ohio, Cincinnati, 1872, a member of the American Medical Association, president of the pension board of Gallia County, Ohio, and formerly assistant physician at the Columbus State Hospital for the Insane, died suddenly from heart disease at his residence in Gallipolis, aged 53.

David R. Francis, M.D. College of Physicians and Surgeons, New York, 1866, aged 60, was found dead in his office in Mansfield, Ohio, June 11, under circumstances suspicious of foul play, as a pocketbook which contained a large amount of money was missing, and as a severe contusion was found on the head.

William Winthrop Betts, M.D. Albany (N. Y.) Medical College, 1883, a specialist on climatology, who was obliged to leave Minneapolis on account of his health, went to Utah, and later to Southern California, died at the Christian Hospital, Los Angeles, June 15, from Bright's disease, after a long illness, aged 41.

Anthony L. Carrick, M.D. College of Physicians and Surgeons, Dublin, Ireland, 1852, of Cincinnati, for two terms coroner of Hamilton County, Ohio, and during the Civil War was surgeon of the Second Tennessee Cavalry, died suddenly from paralysis, June 22, at the home of his son-in-law in East Walnut Hills, aged 79.

Alden Edward Bessey, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1870, a member of the Maine Medical Association, and sometime president of the Kennebec County Medical Society and the Waterville Clinical Society, died at his home in Waterville, Maine, June 15, aged 65.

William Harrison Foster, M.D. Medical College of Georgia, Augusta, 1867, professor of materia medica and therapeutics in that institution, for twenty years city physician of Augusta, died at his home in that city, June 17, from cholera morbus, after a short illness, aged 63.

Delos L. Heath, M.D. University of Michigan, Ann Arbor, 1853, died at his home in Seneca Falls, N. Y., June 10, from heart disease, after an illness of a few weeks, aged 75. During the Civil War he served as surgeon in the Twenty-third Michigan Volunteer Cavalry.

Nelson H. Henderson, M.D. College of Physicians and Surgeons, Chicago, 1886, a member of the American Medical Association, died at the Lakeside Hospital, Chicago, June 23, from septicemia following infection received while operating, May 13, aged 45.

Marion Jasper Dudley, M.D. Macon (Ga.) Medical College, 1856, one of the oldest physicians in the state, a captain-surgeon in the Civil War, and who was born and lived all his life in Gordon County, Georgia, died at his home in Sonoraville, June 20, aged 75.

Thomas J. Buchan, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1884, was shot and instantly killed at his home in Eastman, Ga., June 14, by his son, who was endeavoring to protect his mother from his father's violence.

Charles H. David, M.D. Victoria Medical College, Montreal, P. Q., 1878, a specialist in diseases of the ear, nose and throat, Bridgeport, Conn., died at the home of his brother in Waterbury, Conn., June 18, after a lingering illness, aged 47.

George W. Chrouch, M.D. Middlebury (Vt.) Medical College, died from the effect of an overdose of morphin, at his home in Shaftsburg, Mich., June 19, aged 59. He was a member of the American Medical Association.

Thomas Hammill Hicks, M.D. Medico-Chirurgical College, Philadelphia, 1887, an eminent chemist and metallurgist, died at his home in Fort Wayne, Ind., June 6, from angina pectoris, after a short illness, aged 52.

David B. Fonda, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1878, for four years county physician of Cook County, Ill., died in Jefferson Park, a suburb of Chicago, June 20, aged 68.

Thomas T. Marshall, M.D. Kentucky School of Medicine, Louisville, 1884, died at his home in Floydsburg, Ky., June 26, from abscess of the liver, after an illness of two months, aged 43.

Francis A. Miles, M.D. Medical College of the State of South Carolina, Charleston, 1854, died from paralysis at his home in Greenville, S. C., June 16, after an invalidism of seven years.

Fred C. Miller, M.D. Bennett College of Eclectic Medicine and Surgery, 1883, county physician of Pierce County, Wash., died from diphtheria at his home in Tacoma, June 7, aged 45.

Marion F. Marble, M.D. American Medical College, Cincinnati, 1855, died at his home in Gardiner, Maine, June 15, from paralysis, after an invalidism of fourteen years, aged 77.

Moses J. Bushenville, M.D. Barnes Medical College, St. Louis, 1899, of Bowbells, N. D., died at a hospital in Minot, June 20, from typhoid fever, after an illness of a week, aged 35.

Frank H. Crocker, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1882, died from pneumonia at his home in Gardiner, Maine, after an illness of one week, aged 51.

A. E. Levinson, M.D. University of Minnesota, Minneapolis, of Duluth, Minn., died in St. Mary's Hospital, Duluth, June 19, one day after an emergency operation for appendicitis.

Francis Ferdinand Marshall, M.D. College of Physicians and Surgeons, New York, 1886, of New York City and Jacksonville, Fla., died in the former city, June 21, from cancer.

Harry G. Forrest, M.D. Chicago Homeopathic Medical College, 1893, of Jackson Center, Pa., died at Greenville, Pa., from heart disease, June 9, after a long illness, aged 38.

Edward P. Luce, M.D. Cincinnati College of Medicine and Surgery, 1862, a surgeon during the Civil War, died at his home in Bayonne, N. J., June 12, aged 75.

J. N. Perkins, M.D. Columbus (Ohio) Medical College, a member of the Oregon legislature in 1863, died at his home in Eagle Harbor, Ore., June 10, aged 87.

Theodore Connell, M.D. University of Pennsylvania, Philadelphia, died at the home of his father in Scranton, Pa., June 15, after a prolonged illness, aged 32.

George N. Jennings, M.D. Rush Medical College, Chicago, 1864, formerly of Tonica, Ill., died suddenly from heart disease at Covina, Cal., June 1, aged 65.

John C. Halstead, M.D. New York University, 1883, died at his home in New York City, June 17, after a prolonged illness, from tuberculosis of the bladder.

Jacob A. Bollinger, M.D. Missouri Medical College, St. Louis, 1879, of Oakford, Ill., died, June 3, at the Jacksonville Sanitarium, after a long illness.

Hiram A. Phillips, M.D. University of Louisville, 1875, died at his home in Lexington, Ky., June 18, after an illness of several months, aged 52.

W. T. Herrington, M.D. American Medical College, St. Louis, 1889, died at Grant's Pass, Ore., June 17, from paralysis, after a long illness.

Mordecai J. Ambrose, M.D. Medical College of Ohio, Cincinnati, 1837, died at his home in Cincinnati, June 5, after a long illness, aged 89.

Francis Grandy, M.D. University of Michigan, Ann Arbor, 1852, Fairfield, Mich., died in Adrian, Mich., June 19, aged 75.

Sterling Loomis, M.D. Yale Medical School, New Haven, 1898, died recently from heart disease, aged 30.

Deaths Abroad.

F. Saxer, M.D., professor and prosector at the Institute of Pathologic Anatomy at Leipsic, aged 40. He had been connected with the similar institute at Marburg, and had published many articles on the development of the blood corpuscles and lymph glands, on syringomyelia, gliomata and epithelial tumors of the central nervous system, dermoids and teratomata, pneumonomycosis aspergillina, etc. His death was due to an abscess in the brain, which developed from an apparently insignificant infection of one hand.

M. Huizinga, M.D., formerly professor of physiology at Groningen, died there June 2, aged 63. He was particularly interested in chemotaxis, the physiology of the nerves, albuminoids, peptones, etc., and contributed many articles to science on these subjects as also on ozone from the chemical and biologic standpoints, and on the history of physiology, etc.

Joseph De Smeth, M.D., formerly professor of psychiatry and general pathology at Brussels, died there June 10. He was one of the leading alienists of Europe, and had for many years had charge of the unfortunate Princess Carlotta, widow of Maximilian.

J. Iszlay, M.D., professor of odontology at Budapest.

Miscellany.

The Twenty-fifth Anniversary of Dr. Victor C. Vaughan's Graduation.

On the 18th of June, in the presence of the alumni students, colleagues and friends, a volume of contributions to medical research, containing 34 papers, was dedicated and presented to Dr. Victor C. Vaughan by his colleagues and former students in honor of the twenty-fifth anniversary of his doctorate.

Pres. James B. Angell announced that it was his pleasant duty as official head of the university to express the feelings of the authorities as well as of the alumni and undergraduates on this interesting occasion. The custom, as borrowed from the Germans, of thus recognizing the services of a man who had been of eminence and use was a very pleasant one. He was one of those present who was old enough to remember Dr. Vaughan when the latter was very young. He alluded to the changes that have been made in medical education from what it had been in times past. In earlier times the instruction was very largely given by lectures, and some members of the faculty strenuously urged that it was far more profitable for a student to go through a course and hear the same lectures the second time than to hear them the first time. We must not interpret too literally as correct that view of the case.

The laboratory course had come into use since the period of which he spoke, and it was due very largely to the dean of the department, with doubtless the assistance of his associates, that so great emphasis is now placed on this new and more profitable mode of scientific instruction. He could hardly speak in detail of the important part Dr. Vaughan has played during the past twenty-five years, but it was with very great pleasure that those who had witnessed his career as a student had seen him early fulfilling the promise which he had then given of the brilliant scientific discoveries which he has made, and that that promise had been more than redeemed up to the present time, so that his name is well known, and the name of the medical department of the university through him, not only in this country, but also in all European countries. Dr. Angell said that he was sure that every one connected with the university feels grateful to Dr. Vaughan for the services he has rendered, and they were still glad to look into his face and see that he is still a young man and has doubtless a long career yet before him, and all would be very glad to come here twenty-five years hence to another and more imposing celebration.

Prof. Albert B. Prescott of the University of Michigan made the presentation on behalf of the contributors. Professor Prescott said he was honored in being asked to say something in the presentation of this gift. It was a privilege as well as an honor to speak on the part of those contributors who were the most cherished and influential of the medical alumni of the university. In making this gift a memorial volume had been wrought out piece by piece in the unwearied toil of strenuous life. For its making we have a quarter of a century, a period in the life time of an alumnus, an era in the history of the university. This Festschrift is a symposium of scientific learning, a production of permanent value and an essential record of the advancement of science and of the profession of medicine. It consists of thirty-four separate investigations, each one a chosen product of its author's personal power.

If he were competent to speak of these records of researches, he would not have time to even enumerate them, but he recognized that they were from members who had become authorities in the world, by their work and experience in scientific pursuits. As he looked over the titles he saw that they formed a syposium of research covering the fundamental principles and presenting a series of discoveries, which unite together naturally and inevitably to constitute a tribute of honor to the man to whom the gift was being made. The book belongs to him by virtue of its history and by virtue of its subject matter. It was an acknowledgment of the service he had rendered to the world of science and to the university, to the cause of medical education, to advances in scientific work wherever undertaken.

In accepting the volume Professor Vaughan modestly said that the world had been more than kind to him, that he had received many honors which might have been more worthily worn by others, but he never had received one which he appreciated more highly than the present one. He owed much to the University of Michigan. After he had secured the best education possible in his native state, the state of Michigan offered him what he desired in his further studies and within the range of his scanty purse. Whatever he had done and whatever he might do in the future, will hardly repay the University of Michigan for what it had done for him. That was his feeling toward the university. He also acknowledged his indebtedness to those who make up the university, for their assistance and co-operation, those with whom it had been a pleasure to be and an inspiration to work to be associated with them. Of all the research work he had ever done the greatest and best was that, by the authority of the board of regents, he had been able to collect together a faculty of medicine, every member of which was a master in his specialty. It is easy enough to have a good medical school if you have a good faculty and good students. He owed much to the students, and the spirit for good, honest work, and the inclination to be gentlemanly and honorable had always prevailed among the student body of the university. It was an honor that he had been associated as teacher with some of the greatest scientific men of the country; but they did not owe their eminence to him; they would have been great, and probably greater still, had their instruction been received from others. He wanted to specially express his thanks to him from whose hands he had received this volume. Dr. Prescott was the Nestor of scientific research in the university then as he is now, and from him more than any other man he had received his inspiration. President Angell had explained how his classmates and himself got through the university. It was necessary in order to get them through that the lectures be repeated for two succeeding years, and in this way they were finally nourished sufficiently to become doctors and to be turned out on the world. In accepting this volume he would not regard it as a trophy of any achievement, but as a tribute of love and respect, which he prized more highly than anything else. He expected to derive from it inspiration for further work and find comfort from it in his hours of rest. When he is through with it he will bequeath it to his children as his most valuable earthly possession. He took it that the volume was presented to him as a result of the spirit of scientific research of those who have made these contributions, and he hoped the honorable board of regents would grant him the privilege to give a word of advice and to say that we should encourage the young man who is able to do scientific work. It was not until experimental research came in that the world began to grow and develop. It is scientific research that has made the German universities the centers, not only of science, but of letters as well. Scientific research has not always found a most congenial atmosphere in American universities; it has not always been appreciated as much as it might be. The question is, whether the American university of to-day is to become a center of evolution of knowledge and discovery or only an enlarged and amplified high school. Has not the state the right to ask of its universities the very best knowledge possible on every subject in which the welfare of the people may be involved? In conclusion he said he could not adequately express his feelings, but wished to thank all for this highly appreciated gift.

Medical Organization.

Jackson County (Miss.) Medical Society.

At an adjourned meeting held in Scranton, June 10, the new constitution, in conformity with those of the Mississippi State Medical Association and the American Medical Association, was adopted.

Ellis County (Texas) Medical Society.

Twenty physicians of Ellis County met at Waxahachie, June 16, and organized a county medical society, with Dr. James C. Loggins, Ennis, president, and Dr. Charles W. Simpson, Waxahachie, vice-president.

Jefferson County (Wis.) Medical Society.

Fifteen physicians of Jefferson County met at Watertown, June 16, and organized a county medical society, electing Dr. William W. Reed, Jefferson, president, and Dr. Charles E. Lander, Johnson Creek, secretary.

Chickasaw County (Iowa) Medical Society.

Physicians of Chickasaw County met recently at New Hampton and organized a county medical society, with Dr. Ira K. Gardner, president, and Dr. Nicholas Schilling, secretary and treasurer, both of New Hampton.

Grand Forks County (N. D.) Medical Society.

Twenty physicians of the county met at Grand Forks, June 10, to form a county medical society. A temporary organization was effected, and Drs. Henry H. Healy and John D. Taylor, Grand Forks, and Dr. Willam H. Welch, Larimore, were made a committee on organization to report at a meeting to be held this month.

Hillsborough County (Fla.) Medical Society.

At the regular monthly meeting, held at Tampa, June 2, the constitution and by-laws as recommended by the American Medical Association was unanimously adopted. The following officers were elected: President, Dr. Urban S. Bird; vice-president, Dr. James T. Green; secretary-treasurer, Dr. W. Parks Adamson; board of censors, Drs. W. P. Lawrence, Leslie W. Weedon, and John S. Helms, all of Tampa.

San Luis Obispo County (Cal.) Medical Association.

A number of physicians met at San Luis Obispo, June 6, and organized a county medical association with the following officers: Dr. Joseph S. Jackson, San Luis Obispo, president; Drs. John K. McLennan, Paso Robles, and Byron F. Dawson, Cayucos, vice-presidents; Dr. E. A. Dial, San Luis Obispo, secretary, and Dr. J. J. Knowlton, San Luis Obispo, treasurer. The association will apply for affiliation with the state medical society.

Fairfield County (Ohio) Medical Society.

Under the direction of Dr. Theodore W. Rankin, Columbus, the physicians at Fairfield County organized a county medical society at Lancaster, June 16, with the following officers: President, Dr. John H. Goss, Lancaster; vice-president, Dr. George S. Courtright, Lithopolis; secretary, Dr. George O. Beery, Lancaster; treasurer, Dr. Samuel Renshaw, Sugar Grove, and censors, Drs. John J. Silbaugh, Lancaster; Oliver P. Driver, Bremen, and E. N. Heston, Thurston.

Pottawatomie County (Iowa) Medical Society.

About 40 physicians of the county met in Council Bluffs, June 17, and organized a county medical society, with Dr. Donald McCrae, Council Bluffs, president; Dr. Samuel W. Tobey, Oakland, vice-president; Dr. F. W. Dean, Council Bluffs, secretary; Dr. Grant Augustine, Minden, treasurer, and Dr. Henry B. Jennings, Council Bluffs, delegate to the Iowa State Medical Society. The society adopted the constitution and by-laws suggested by the American Medical Association.

Indianapolis Medical Society.

At its meeting held June 23, the Indianapolis Medical Society-The Medical Society of Marion County, Ind., by unanimous vote, adopted the constitution and by-laws as suggested by the American Medical Association. While the constitution and by-laws of the Indianapolis society were satisfactory to the local profession, yet in the interests of uniformity and harmonious work, and to set an example which would influence other societies, this body cheerfully fell in line with the new movement in this respect, as it is doing in others. The membership of this society has now reached 220, and it is hoped to greatly increase this number in the immediate future.

Societies.

Butler County (Pa.) Medical Society.—At the annual meeting, Dr. John E. Byers was elected president; Dr. Robert J. Grossman, vice-president, and Dr. William B. Clark, secretary, all of Butler.

Newcastle County (Del.) Medical Society.—At the annual meeting in Wilmington, June 19, Dr. Frank Belville, Delaware City, was elected president; Dr. R. Raymond Tybout, Wilmington, secretary, and Dr. Peter W. Tomlinson, Wilmington, treasurer.

Southern Oregon Medical Association.—The twelfth annual meeting was held in Medford, May 12. Dr. H. Percival Hargrave, Phoenix, was elected president; Dr. George E. Houck, Roseburg, vice-president, and Dr. Robert E. Smith, Grant's Pass, secretary and treasurer.

West Tennessee Medical Association.—The twelfth annual meeting was held in Jackson, June 11 and 12. The following officers were elected: Dr. William T. Watson, Lexington, president; Drs. D. Warren Scates, Martin, and Robert W. Tate, Bolivar, vice-presidents, and Dr. Isaac A. McSwain, Paris, secretary and treasurer.

Southwestern Kentucky Medical Society.—This society met, May 12 and 13, at Paducah, and elected the following officers: Dr. Horace T. Rivers, Paducah, president; Drs. E. B. Shelton, Blandville, and Charles N. Crawford, Lynn Grove, vice-presidents; Dr. Van A. Stilley, Benton, secretary, and Dr. Charles H. Brothers, Paducah, treasurer.

Spokane County (Wash.) Medical Society.—At the annual meeting held in Spokane, May 7, the following officers were elected: Dr. Edwin L. Kimball, Spokane, president; Drs. Harry S. Martin, Spokane, and H. H. Slater, Deer Park, vice-presidents; Dr. George A. Gray, Spokane, secretary, and Dr. William L. Hall, Spokane, treasurer.

Gibson County (Tenn.) Medical Society.—The semi-annual meeting was held in Humboldt, June 19. Dr. John T. Faucett, Trenton, was elected president; Dr. Benjamin S. Penn, Fruitland, vice-president; Dr. Basil T. Bennett, Trenton, secretary and treasurer, and Dr. George W. Penn, Humboldt, representative to the Tennessee State Medical Association.

Worcester North District (Mass.) Medical Society.—The forty-fifth annual meeting was held in Worcester April 28. Dr. H. Porter Hall, Leominster, was elected president; Dr. Edward A. Sawyer, Gardner, vice-president; Dr. Walter S. Sawyer, Fitchburg, secretary; Dr. Eustace L. Fiske, Fitchburg, treasurer, and Dr. Luther G. Chandler, Townsend, commissioner of trials.

Medical Society of the State of North Carolina.—To complete the report which appeared in THE JOURNAL of June 20, the election of Drs. John H. Williams, Asheville; John C. Rodman, Washington, and S. Fred Pfohl, Winston, as vice-presidents, and of Drs. J. Howell Way, Waynesville, and Albert Anderson, Wilson, as members of the House of Delegates, must be noted. In 1904 the society will meet in Raleigh, on June 1.

Southern California Medical Society.—The thirty-first semi-annual meeting was held in Avalon, Santa Catalina Island, June 3 and 4. The following officers were elected: President, Dr. John C. King, Banning; vice-presidents, Drs. Frank Garcelon, Pomona, and Luther M. Powers, Los Angeles, and secretary and treasurer, Dr. Frank D. Bullard, Los Angeles. The next meeting will be held at Redlands in December.

North Missouri Medical Association.—At the annual meeting held in Columbia, June 19, the following officers were elected: President, Dr. W. V. Yates, Callao; vice-presidents, Drs. Edwin S. Cave, Mexico, and A. N. Wood, Sumner; corresponding secretary, Dr. William O. Hawkinson, Roanoke; recording secretary, Dr. J. H. P. Baker, Salisbury, and treasurer, Dr. Robert Haley, Brookfield, (re-elected). Kirksville was selected as the place for the next meeting.

Norwich (Conn.) Medical Association.—On May 18 this association celebrated its twenty-fifth anniversary. The exercises consisted of an address of welcome by the president, Dr. Patrick Cassidy; a historical sketch of the society by the secretary, Dr. Rush W. Kimball, and an address by Dr. W. Gilman Thompson, New York City, on "The Clinical Value of Recent Laboratory Tests." About 50 physicians of Eastern Connecticut were present at the banquet which followed.

Wayne County (N. Y.) Medical Association.—At the annual meeting held in Lyons, June 2, Dr. James W. Putnam, Lyons, was elected president; Dr. Mary A. Brownell, Newark, vice-pres-

ident; Dr. George S. Allen, Clyde, secretary, and Dr. Darwin Colvin, Clyde, treasurer. Drs. Jennie M. Turner, Lyons, Lucius H. Smith, Palmyra, and John T. Myers, Sodus, were added to the executive committee, and Dr. Thomas H. Hallett, Clyde, was made a member of the nominating committee, Fourth District Branch.

Congress of Dermatology.—Unusual inducements are offered to members of this congress, which will meet at Sarajevo, Bosnia, September 21 to 23. The Bosnian government has offered a free special train from the borders of Bosnia to Sarajevo, and for several excursions to other points. Very moderate stipulated charges in the hotels are also promised. By invitation of the Hungarian confrères at Budapest, the members are to spend a day there on their way to the congress. Dr. L. Glück of Sarajevo is at the head of the executive committee of the congress.

Association of Medical Officers of the Army and Navy of the Confederacy.—The sixth annual meeting was held in New Orleans, May 19, 20, 21 and 22. The election of officers resulted as follows: Dr. Stanford E. Chaille, New Orleans, who, on account of age and infirmity declined, whereupon Dr. John R. Gildersleeve, Tazewell, Va., was elected; Drs. James D. Croom, Maxton, N. C., William E. Brickell, New Orleans, F. R. Calhoun, Cartersville, Ga., and James M. Holloway, Louisville, Ky., vice-presidents, and Dr. Deering J. Roberts, Nashville, Tenn., secretary and treasurer (re-elected).

Naturforscher Congress.—The seventy-fifth annual congress of the German Association of Physicians and Naturalists will be held this year at Cassel, convening September 21 to 26. The Berlin professor of chemistry, van t'Hoff, will preside. The addresses at the two general meetings will be by Behring on "Tuberculosis," Griesbach on "School Hygiene," Ramsay, London, on the "Periodical System of the Elements" and by Ziehen, Utrecht, on the "Physiologic Psychology of Sentiments and Sensations." Radiotherapy will be the chief theme in the medical section, with addresses by Jensen and Rieder. These congresses are always attended by thousands and have been important landmarks in the history of science in Germany. The aim is to bring together theory and practice, the laboratory worker and the general practitioner, with scientific workers of all kinds. Penck, Vienna, will deliver an address on "Geologic Time"; Schwalbe on the "Prehistoric History of Man," and Alsberg on "Hereditary Degeneration in consequence of Social Influences."

Medical Society of Delaware.—The one hundred and fourteenth annual meeting was held in Dover June 9. Dr. George W. Marshall, Milford, made a report of the meeting of the American Medical Association, to which he was a delegate. The following officers were elected: Dr. Harry G. M. Kollock, Newark, president; Drs. Paris T. Carlisle, Frederica, and Laurence M. Cahall, Bridgeville, vice-presidents; Dr. John Palmer, Jr., Wilmington, secretary; Dr. Joseph M. Martin, Lewes, assistant secretary; Dr. William C. Pierce, Wilmington, treasurer; Drs. Henry J. Stubbs, Wilmington, Joseph R. Smith, Cheswold, and David Hall, Lewes, councilors; Dr. George W. Marshall, Milford, delegate to the American Medical Association, and Dr. Willard Springer, Wilmington, alternate. It was decided to submit to the governor the following names from which to select members of the State Board of Medical Examiners: Drs. Ezekiel W. Cooper, Camden; Francis L. Springer, Newport; Henry W. Briggs, Wilmington; L. August H. Bishop, Dover; Robert G. Ellegood, Concord; William T. Skinner, Glasgow; Charles Green, Greeneville; John Palmer, Jr., Wilmington; Oliver D. Robinson, Georgetown, and David Hall, Lewes. Resolutions were adopted favoring legislation looking to the examination of the eyes and ears of school children. The society adjourned, to meet at Lewes, June 14, 1904.

MASSACHUSETTS MEDICAL SOCIETY

One Hundred and Twenty-second Annual Meeting, held in Boston, June 9 and 10, 1903.

The President, Dr. George E. Francis, Worcester, in the Chair.

First Day.

The morning of the first day was devoted to visiting hospitals and dispensaries. At 2 p. m. the society met in two sections at the Medical Library on the Fenway.

Examination of Stomach Contents.

DR. ELLIOTT P. JOSLIN, Boston, speaking on "Inferences to Be Drawn from the Examination of the Contents of the Stomach," explained how simple are the tests necessary for such examination of the fluid obtained by the stomach tube from the fasting stomach, and pointed out the great aid thereby gained for diagnosis and treatment. His paper was ably discussed by Dr. R. H. Chase.

Dietetic Treatment of Constipation.

DR. HENRY F. HEWES, Boston, maintained that nearly every case of constipation can be controlled by adding to the diet suitable quantities of cereals, fats, vegetables, fruits or fermenting carbohydrates, using only as a last resort senna in stewed prunes.

Surgical Treatment of Gastric Ulcer.

DR. JOHN C. MUNRO, Boston, urged the joint study of every case by the physician and surgeon. Most cases are medical, but in those cases which are not, operation should be done early. Great advances have been made in the surgery of the stomach in the last three years.

Section in Surgery.

In this section the chief papers were on "Rupture of the Quadriceps Extensor Muscle," "Surgery of the Esophagus," "Prostatectomy," and "Adeno-Carcinoma of the Intestine." These papers were much more freely discussed than those in the medical section, the meeting adjoining only when it was necessary for the councilors to meet.

Councilors.

About 100 members of this representative body met to transact the necessary annual business of the society. The secretary reported the addition of 173 new members during the past year and the death of 42. The treasurer reported a balance of $11,289 on hand, total disbursements of over $26,000, and permanent funds amounting to $37,494.

Arrangements for 1904.

It was voted that the next meeting be held on the second Wednesday in June, 1904, in Boston. The Shattuck Lecture for 1904 will be given by Dr. Juan Guiteras. Dr. Harold C. Ernst, Boston, was elected orator for next year. The officers were re-elected with the exception of vice-president, for which office Dr. J. F. Alleyne Adams, Pittsfield, was chosen.

Shattuck Lecture.

The Shattuck Lecture was given in the John Ware Hall in the Medical Library by Dr. Theobold Smith, Boston, on "The Sources, Favoring Conditions and Prophylaxis of Malaria in Temperate Climates, with Special Reference to Massachusetts." It was a most exhaustive paper, the result of eight or ten years' study of the subject, and was illustrated by lantern views. Considerable portions were omitted in the reading. The author believes that "there is no evidence, experimental or otherwise, that the malaria germs exist outside of their hosts, man and the mosquito." He endeavored to explain immunity, and dwelt on the latent character of the disease, maintaining that infected human beings must be the starting point for any epidemic. Early malaria came from the Indians. Later we have derived it from Italian, Hungarian and negro laborers.

Tobacco and the Heart.

DR. RALPH C. LARRABEE, Boston, said the action of the heart is reduced by even moderate amounts of nicotin, the effect being noticed very quickly. Tobacco smoke contains, he said, from nothing to 50 per cent. of nicotin. Allowing that smoking must prevail, he would advise smokers to use long-stemmed pipes and to keep them clean, and not to smoke cigars too close to the end. No harm will result, he said, from suddenly and completely ceasing the smoking habit.

Posture in Gynecology.

DR. DANIEL H. CRAIG, Boston, demonstrated that the abdominal pressure induced by coughing, sneezing and straining in women suffering from pulmonary disease probably has a large influence in determining displacements of the pelvic viscera, notably the ovary and uterus.

Anatomy Not an Exact Science.

DR. THOMAS DWIGHT, Boston, presented a paper on "Problems of Clinical Anatomy," in which he effectively disposed of

the idea that anatomy is a completed exact science. He showed by large models what wide variations may exist in skull, vertebræ, aorta and tarsal bones, and explained how surgeons, not knowing of these frequent variations, are misled by *x*-ray photographs.

Privileged Communications.

DR. DAVID W. CHEEVER, the "Nestor" of Boston physicians, was greeted with much applause when he came forward to make "A Plea for a Change in the Massachusetts Law in Regard to Privileged Communications." He maintained that the adage of Hippocrates, "Nothing heard in the sick-room should ever be heard outside of it," should be put in practice legally, unless, 1, the patient consented; 2, it was necessary for the doctor's self-defense, or 3, it was necessary to expose crime. All New England and nearly half the states of the Union are following the English law, which obliges the physician to disclose in the courts of justice such information as may have been acquired in a professional capacity, even if it involves the character of the patient's family or disgraces the memory of the dead. New York and about one-half of the states in the Union have adopted the Roman law, which not only exempts the physician, but forbids him from disclosing such information. He pleaded for a change in the Massachusetts laws bearing on this subject, and he suggested that if confidential communication must be disclosed as an aid to justice it should be communicated to the judge in private.

WALTER SOREN, ESQ., Brookline, showed "The Workings of the New York Law," which was devised to protect the patient, and quoted a large number of cases and decisions by the New York courts as determining three points: 1, when the relations of physician to patient become "professional"; 2, what information obtained during this professional relation is excluded, and 3, what information is necessary to the physician to enable him to act.

Tuberculosis.

DR. HERBERT L. BURRELL, Boston, delivered the annual address on "Tuberculosis" and illustrated by numerous lantern views. He said:

> The line along which we should work is that of giving the patient greater resistance to the disease. This can be done especially through the use of sanatoriums and other special methods of treatment, including all forms of outdoor treatment. These methods were widely adopted in Germany, where the sanatoriums were supported from the reserve of $175,000,000 fund accumulated as a result of the Bismarck laws regarding insurance of working people. In Germany, moreover, an amount of attention had been given to tuberculosis by the insurance companies that might well be imitated here. There is now a drift of opinion toward the view that change of climate is not so important as other methods of dealing with the disease. Hospitals, with few exceptions, recognize the necessity of outdoor treatment. Sometimes, as in Germany, the patients are kept out of doors all night. Yet, thus far, outdoor life for consumptives is not adequately recognized. There are two errors which continue to be associated with the outdoor treatment—the sending of patients to sanatoriums when they are in an advanced stage of the disease, and failure fully to recognize in the treatment of consumptives the physiologic value of rest.

He urged physiologic rest for the affected organ or part, whether treated medically or surgically, and pointed out the great benefits to be obtained from sunshine, air, diet and care in sanatoria.

Entertainment.

The festivities of the meeting which began in the Cotting lunch, served immediately after the councilors' meeting, repeated in the evening at the reception to the officers, ended at 1 p. m., Wednesday, in the annual dinner served in Symphony Hall, where over 1,200 physicians dined together. After-dinner toasts were responded to by Attorney-General Parker, Rev. M. H. Hall and others.

BUFFALO ACADEMY OF MEDICINE.

Regular Meeting, held May 20, 1903.

Dr. Herman E. Hayd, Chairman, presiding.

Early Diagnosis of Gastric Cancer.

PROF. C. A. EWALD, Berlin, delivered an address on this subject. Since the great strides made in recent years in the domain of abdominal surgery the question of an early diagnosis by the internist of gastric carcinoma has become an important one, for if the case can be correctly diagnosed sufficiently early before metastases have occurred the surgeon may radically remove the growth and the case may result in recovery.

There are cases which show one or all of the following symptoms: 1, A tumor; 2, swelling of nodes, axillary, inguinal, etc.; 3, cachexia, and 4, changes in secretion. These cases are not difficult of diagnosis, but when diagnosed it is too late for radical operation.

Early Symptoms.

The question of early symptoms should be considered when the tumor is not far advanced, when no metastases exist and where there is a possibility of the removal of the growth in its entirety.

The school of Kaussmaul and von den Velden wanted to prove that wherever free HCl was diminished or absent it was sufficient to diagnose cancer of the stomach, but Ewald demonstrated many cases where, although there was an absence or diminution or free hydrochloric acid secretion, they were not cancer, as, for example, neuroses, achylia gastrica, etc.

Boas stated that the presence of lactic acid was an important symptom for cancer. This also has been proven a mistaken belief, for lactic acid depends on one or all of three conditions: 1, No hydrochloric acid secretions; 2, stagnation of gastric contents, and 3, no peptic enzymes. When these three conditions present themselves lactic acid is formed, and it may exist in cases other than cancer. A case of cancer of the gall bladder with pyloric obstruction due to pressure and secondary dilatation of the stomach was cited where lactic acid was present, and where no cancerous infiltration of the stomach could be detected on postmortem examination. The same conditions which apply to the value of lactic acid apply also to the thread-like Oppler-Boas bacilli, which are a lactic-acid forming bacilli.

Gastric Ulcer and Cancer.

Rokitansky and other pathologists showed years ago that many cases of gastric ulcer are transformed in time to carcinoma. If, then, we could detect this transformation sufficiently early an early diagnosis of gastric cancer could be made. In ulcer there is hyperchlorhydria; so soon as the metamorphosis to cancerous degeneration occurs the hydrochloric acid is diminished or disappears. Cases of chronic ulcer going on slowly and which in time give suspicious signs of cancer may be detected if the gastric contents are analyzed and alteration of secretion is noted.

A Polish physician, Gluczinski of Cracow, by making three analyses of stomach conditions: 1, The fasting stomach; 2, after the Ewald test breakfast, and 3, after a more complete meal, found that if these analyses gave the same results of hypersecretion then the ulcer still existed; if, on the other hand, there were variations, say hypochlorhydria or absence of HCl in one or two or three of the test meals, then a suspicion of a beginning cancerous degeneration existed. Gluczinski operated on one case in which after these test meals a suspicion of cancer was diagnosed, and found a beginning degeneration from ulcer to cancer.

Case Report.

Ewald used this method in four cases and gives his result in one:

> CASE 1.—Man; aged 39; father had cancer of stomach. Patient has complained for several years of oppression after meals, nausea, eructation and vomiting of undigested stomach contents. He is emaciated, has lost weight. No tumor was detected and there was no glandular enlargement. He had vomited blood once. This probably came from the stomach. The stomach was dilated and there was succussion. Tests were made after Gluczinski. Acidity, 60; mucus and slow digestion of mucus. The fasting stomach showed mucus and no acidity; Ewald's acidity, 72; free hydrochloric acid, 50. After a full meal acidity, 28; no free HCl, but combined HCl.
>
> As a result of these examinations and the history, the case was diagnosed as early carcinoma of pylorus. The operation of pyloric resection and gastroenteric anastomosis was performed by Professor Krause. The patient made a complete recovery. Macroscopic and microscopic examination of the pyloric sclerosed tissue failed to reveal carcinoma. The case was a hypertrophic enlargement of muscles of pylorus which often follows gastric ulcer, so in this case the method described by Gluczinski failed.

Tryptophan Test.

A new method has lately been described by Dr. Glässner, assistant to Ewald. It is called the tryptophan reaction. Into

a small vessel containing 10 to 20 c.c. of filtered stomach contents containing free hydrochloric acid, place a small piece of carcinomatous tissue. A glass tube filled with albumin is then placed into this vessel. After a time—about 24 hours—both ends of the albumin tube will show a digestion of the albumin. If the solution is then filtered and a solution of bromin is added, a red coloration will show the tryptophan reaction. If the tissue added is cancerous, this reaction follows, if not, no reaction takes place.

As yet the number of cases in which this test has been made are not large enough to make positive statements as to its value.

Must Rely on Old Methods.

Professor Ewald believes that we still have to rely on other methods for our diagnosis, for after all we must fall back to the detection of the tumor for diagnosis, so that he who is well trained to examine the abdomen by palpation, percussion, etc., will be better able to detect a growth earlier than he who does not practice this form of examination. He recommends that by examining a patient in a warm bath the muscular rigidity may be overcome and more satisfactory results obtained in detecting a growth. He also often uses an ether spray in a circumscribed area over the region of the tumor to relax the muscles.

Epochs of American Medicine.

In conclusion Professor Ewald spoke in laudatory terms of the American institutions which he had visited. He spoke of these epochs of American medicine: 1. When instruction was sought in England; 2, when American physicians visited the French masters, and 3, the present or German epoch. He predicted that in the near future, with the great advances in the medical art in America, the tide would turn and that continental students would seek American institutions and medical education.

Luncheon for Professor Ewald.

Following the address Dr. A. L. Benedict gave a luncheon for the members in honor of Professor Ewald.

NEW YORK STATE MEDICAL ASSOCIATION.

Nineteenth Annual Meeting of the Fourth District Branch, held at Buffalo, N. Y., June 16, 1903.

The President, Dr. J. William Morris, Jamestown, in the Chair.

President's Address.

The president made a brief report of the work which had been done in the past year. At the last annual meeting only three counties—Erie, Chautauqua and Steuben—were represented. This year ten counties were represented by delegates. Last year the membership was 176; at this meeting it was 336. There are still four counties in the district—Ontario, Yates, Livingston and Niagara—which are unrepresented, but he expressed the hope that delegates from these counties would be present at the next meeting.

Election of Officers.

The following officers were re-elected: President, Dr. J. William Morris, Jamestown; vice-president, Dr. Bernard Cohen, Buffalo, and secretary, Dr. William J. Thornton, Buffalo. Dr. Henry A. Eastman, Jamestown, was elected treasurer. Drs. Alvin A. Hubbell, Buffalo, and George L. Preston, Canisteo, were elected delegates to the state association. The following were elected members of the executive committee: Drs. George H. Witter, Allegany County; William H. Vincent, Cattaraugus County; Orrin T. Shaw, Chautauqua County; Allen A. Jones, Erie County; Albert P. Jackson, Genesee County; Thomas A. O'Hare, Monroe County; Edward Munson, Orleans County; Charles O. Green, Steuben County; James W. Putnam, Wayne County, and Philip S. Goodwin, Wyoming County. The committee on arrangements for service for the ensuing year is made up as follows: Drs. J. William Morris, Jamestown; Allen A. Jones, Alvin A. Hubbell, George A. Himmelsbach, William I. Thornton, Bernard Cohen Arthur G. Bennett, Grover W. Wende and William J. Thornton, Buffalo.

Significance of Uterine Retrodisplacements.

Dr. Samuel M. Brickner, New York City, read a paper on "The Obstetrical Significance of Retroversion and Retroflexion of the Uterus," which was a strong argument against the retention of the dorsal posture after childbirth. He declared that too many physicians insisted on keeping their patients on their backs too long after childbirth.

Dr. Carlton C. Frederick, Buffalo, said that, other things being normal, he never insisted on any particular attitude in bed, so long as the patient remained in bed, but that he was opposed to keeping patients in the dorsal position.

Cancer of the Lungs.

Dr. John Herr Musser, Philadelphia, President-elect of the American Medical Association, delivered the principal address of the afternoon, which dealt with the most recent conclusions and discoveries in relation to malignant disease of the lungs, and reported three cases of cancer of the lungs which had come under his observation, one of which bore a close similarity in its symptoms to tuberculosis. Dr. Frederick Holme Wiggin, New York City, president of the New York State Medical Association, accompanied Dr. Musser to Buffalo and participated in the discussion which followed his address.

Banquet.

A dinner was given at the Iroquois in the evening in honor of Dr. John Herr Musser of Philadelphia, President-elect of the American Medical Association, and Dr. Frederick Holme Wiggin of New York City, president of the New York State Medical Association. Dr. Allen A. Jones, Buffalo, was toastmaster, and informal addresses were made by the presidents of the Fourth District Branch Association, the New York State Medical Association and the American Medical Association.

NEBRASKA STATE MEDICAL SOCIETY.

Thirty-fifth Annual Meeting, held at Lincoln, April 28 to 30, 1903.

The President, Dr. Allen B. Anderson, Pawnee City, in the Chair.

Welcome.

Rev. H. C. Swearingen, Lincoln, welcomed the society on behalf of the city, and Dr. Robert C. McDonald, Fremont, responded for the society, thanking the citizens for the cordiality and sincerity of their welcome.

Reorganization.

The Committee on Reorganization recommended, by its chairman Dr. Alexander S. Von Mansfield, Ashland, adoption by the society of the constitution and by-laws suggested by the American Medical Association. Fifty-nine counties of a possible sixty-five made the necessary organization in anticipation of the reorganization. The state is divided into twelve councilor districts, containing the following counties:

No. 1.—Douglas and Sarpy.
No. 2.—Lancaster, Cass and Otoe.
No. 3.—Gage, Johnson, Nemaha, Pawnee and Richardson.
No. 4.—Knox, Cedar, Dixon, Dakota, Antelope, Pierce, Wayne, Thurston, Madison, Stanton and Cuming.
No. 5.—Burt, Washington, Dodge, Colfax, Platte, Boone, Nance and Merrick.
No. 6.—Saunders, Butler, Seward, Polk, York and Hamilton.
No. 7.—Clay, Fillmore, Saline, Nuckolls, Thayer and Jefferson.
No. 8.—Cherry, Keya Paha, Boyd, Brown, Rock, Holt, Grant, Hooker, Thomas, Blaine, Loup, Garfield and Wheeler.
No. 9.—Custer, Valley, Greely, Sherman, Howard, Dawson, Buffalo and Hall.
No. 10.—Gosper, Phelps, Adams, Furnas, Harlan, Franklin and Webster.
No. 11.—Red Willow, Hitchcock, Dundy, Chase, Hayes, Frontier, Lincoln, Perkins, Kieth, Arthur, McPherson and Logan.
No. 12.—Deuel, Sheridan, Dawes, Box Butte, Sioux, Scottsbluff, Banner, Kimball and Cheyenne.

The report of the committee and the new constitution and by-laws were adopted.

A scientific program of the usual number of papers was read and discussed. The society more than doubled its membership and the attendance was larger than any previous meeting.

Election of Officers.

Officers for the ensuing year were elected as follows: President, Dr. Benjamin F. Crummer, Omaha; vice-presidents, Drs. G. W. Shidler, York, and P. Emmett Plumb, Gothenburg; secre-

tary, Dr. A. D. Wilkinson, Lincoln (re-elected); corresponding secretary, Dr. H. Winnett Orr, Lincoln (re-elected); treasurer, Dr. James L. Greene, Asylum (re-elected); and councilors: First district—Dr. Byron B. Davis, Omaha; second district—Dr. Albert R. Mitchell, Lincoln; third district—Dr. John W. Bullard, Pawnee City, and fourth district—Dr. Edward Tanner, Battle Creek. The other eight councilors hold over. Omaha was selected as the place of the meeting for 1904..

NORTHWEST MEDICAL SOCIETY OF PHILADELPHIA.

Regular Meeting, held May 5, 1903.

The President, Dr. Wm. Egbert Robertson, in the Chair.

Treatment of Tapeworm.

DR. SAMUEL P. GERHARD read a paper in which he called attention to the three specimens which were most commonly met, i. e., the beef tapeworm or *Tænia saginata*, the pork tapeworm or *Tænia solium*, and the broad tapeworm or *Bothriocephalus*, the former being the one most commonly met in this country. He called attention to the necessity of thoroughly cooking the meat before it is eaten, which, together with cleanliness on the part of those engaged in handling it, and systematic and regular inspection of the cattle and the meat after it is in the market, he believed would materially decrease the number of cases of this condition. He remarked on the difficulty in removing the worm and considered that the treatment which was applicable to worms of one character was applicable to all. The preparation of the patient prior to the administration of the remedy he considered a most important factor; the patient should be required to fast for twenty-four hours before the medicine is administered, during which time the bowels should be thoroughly emptied by means of purgatives. Among the drugs mentioned were the male fern, the bark of the pomegranate, and its alkaloid, pelletierin; the last two, however, are very impalatable and may produce toxic effects in doses large enough to be effective. Oil of turpentine, while formerly used to a great extent, owing to its nauseating taste and difficulty of administration, has somewhat fallen into disuse. Kamal is a very active drug, but its use is contraindicated, because it causes nausea and vomiting in many instances. Powdered pumpkin seeds were thought to be a valuable and harmless remedy, especially in children. He emphasized particularly the importance of removing the whole worm in all cases, for if the head or any of the segments remain it will develop again in from six to eight weeks. He believed that the great drawback to the administration of many of the remedies was the very large dose required, being in some instances as much as a pint of a bitter nauseating liquid, to be taken at one or two draughts, necessitating loss of time, and being a very serious matter with a weak and debilitated patient.

He reported a method which he had found very satisfactory. The patient is instructed to thoroughly clean out the bowels by purgatives the day previous to the administration of the remedy. In the morning, as early as possible, a twenty-grain capsule of pelletierin tannate is given, and after this has operated fully, which is usually in about two or three hours, the following prescription is administered:

℞. Olei resinæ aspidii
Etheris, āā 3ii
Hydrargyri chloridi mitis .....gr. xii

This is divided into sixteen capsules and one given every ten minutes, no food being taken. In about two or three hours the worm will be expelled whole, with its head intact. He stated that he had recently employed this method in seven cases, with very satisfactory results; the depression is generally very slight and does not last longer than two or three hours, and if it does exist light food can be administered after the worm is expelled.

DR. L. NAPOLEON BOSTON gave a microscopic exhibition of intestinal parasites, consisting of the beef worm, trichina, echinococcus and ankylostoma.

DISCUSSION.

DR. A. C. MORGAN stated that he had used the remedies recommended with very satisfactory results. He believed that a positive diagnosis of tapeworm should not be made unless the segments were found in the stool, although the larvæ are not discoverable there. He referred to the predisposition of the embryo of various worms to lodge in the pectoral muscles, the biceps, the diaphragm and particularly under the tongue, and in a patient suffering from what is apparently muscular rheumatism, but in reality larvæ, there will be irregular temperature, some fever and increased pulse. Interference with the action of the diaphragm, tenderness of the various muscles and symptoms of pleurisy are also important diagnostic symptoms. He believed that the oil of turpentine was contraindicated, if the kidneys were not in perfect working order.

DR. SAMUEL WOLFE referred to the difficulty of diagnosis of this condition, as the various forms of intestinal parasites do not give rise to particular symptoms, and the conclusion can probably only be positively reached after seeing a worm, and the condition may exist for a considerable time without any being passed. He felt that they were more apt to occur during some acute infectious disease, or some decided constitutional disturbance, especially when the disease has assumed the malignant form, he having observed in several instances during the infection that worms were passed in very large numbers. In cases of tapeworm, he believed, if the worm was of any size, segments would usually be discoverable in the stools.

DR. LUTHER C. PETER attributed poisonous effects to the castor oil which was administered in most cases.

DR. GIBBON reported the case of a child who, during the three or four months previous to the passing of segments, had been given raw Hamburg steak. He also referred to a case which had come under his observation in the Children's Hospital, where a child was seized with coughing and the nurse removed one or two large worms from its mouth. He believed that the migration of the worms was particularly common in typhoid fever, in some cases causing the perforation.

DR. HARRY LOWENBURG reported the case of a Polish child who was brought to him a short time ago suffering from hematemesis. Being familiar with the fact that these people fed their children on raw pork, he at once administered an emetic, which was followed by the vomiting of a large round worm, about four inches long, after which all the symptoms disappeared.

DR. CHARLOTT reported the case of a girl operated on in the German Hospital, after which she vomited a large number of worms.

DR. ARTHUR P. HITCHENS suggested the possibility of the remedy being absorbed before it reached the intestinal tract unless it was given in capsule form, which method he believed would be the most efficient.

DR. WM. EGBERT ROBERTSON recommended the more frequent examination of the stools, which he believed would lead to the detection of the ova of the round worm in many instances. While the flat worm is rare in children, he referred to a case reported by Dr. D. J. Milton Miller, occurring in a child eight months old, who was supposed to be infected by feeding it on expressed beef juice.

DR. L. NAPOLEON BOSTON stated that in cases of trichina there is always a swelling and pain in the frontal region. He believed that the *Oxyuris vermicularis* was quite as common in adults as in children, and while the habits of the patient may have had a great deal to do with its occurrence, he did not feel that the social class had. Examination of the rectal mucus prior to the commencement of treatment was recommended in all cases.

DR. SAMUEL P. GERHARD believed that many cases were diagnosed as *Tænia solium*, which in reality were worms of a different character. He believed that the reason this condition was not so prevalent in this country was due to the fact that people had been taught to cook pork thoroughly, while they eat raw beef, which accounts for the more frequent occurrence of that variety. Ether he believed to be of value, as it tended to stupify the worm, and in that way facilitate its removal, and he also felt that it was important that the worm should be passed into a vessel of warm water, for if the temperature is lower than that of the intestinal tract it is liable to recede.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

The Nitrites and Nitroglycerin.

There are probably no preparations which more certainly produce positive results when administered than do amyl nitrite and nitroglycerin. The physiologic action of these preparations is similar, such as producing fulness in the head, flushing of the face, a general dilatation of the peripheral vessels and acceleration of the pulse and respiration. As a result of this arterial dilatation the blood pressure is lowered.

These preparations are of great value in the treatment of angina pectoris to relieve the arterial spasm either by inhaling the amyl nitrite dispensed in pearls or by the internal administration of nitroglycerin. The latter preparation is of service in relieving the labor of the heart, which has already undergone great changes in chronic interstitial nephritis. Under such circumstances the marked arterial tension so characteristic of this disease is greatly lowered and the labor of the left heart decreased. Nitroglycerin is also of service in some cases of pneumonia where digitalis is indicated, in order to counteract the effects of the latter preparations on the peripheral circulation. In other words, it should be remembered that the nitrites are only indirect heart stimulants owing to the fact that they decrease the labor of the heart by lessening the resistance in the arterial rather than by stimulating the heart muscle, as does digitalis. So that in those conditions accompanied by high aortic resistance they can be employed to advantage.

In asthmatic attacks accompanied by spasm of the bronchioles relief is promptly given by the nitrites.

In cerebral hemorrhage it is supposed to decrease the tendency to greater hemorrhage by so dilating the visceral blood vessels as to decrease the blood pressure in the cerebral circulation. In cirrhotic kidney the following combination was a favorite of Da Costa:

℞.	Nitroglycerini .....gr. 1/100	0006
	Tinct. digitalis	
	Tinct. strophanthi, āā.....m. ii	12
	Tinct. belladonnæ .....m. ss	03

M. Ft. cap. No. i. Sig.: Take one such every six hours.

In asthma the following combination containing glonoin is recommended by Hare:

℞.	Pot. iodidi	
	Sod. brom., āā .....gr. iii	20
	Nitroglycerini .....gr. 1/150	00045
	Tinct. lobeliæ .....m. ii	12

M. Ft. tabella No. i. Sig.: One such four or five times a day.

The following containing sodium nitrite is also of service in asthma:

℞.	Chloralis hydratis 3iii	12
	Sodii nitritis 3ss	2
	Tinct. stramonii 3i	4
	Syr. glycyrrhizæ q. s. ad.....℥ii	60

M. Sig.: One teaspoonful every four hours.

The following combinations containing powdered niter is recommended to relieve asthmatic attacks:

℞.	Stramonii flores.....3ii	8
	Cannabis ind. flor. 3iss	6
	Pulv. niter .....℥iss	45
	Olei eucalyptus .....℥ss	2

M. Ft. pulvis. Sig.: Place one teaspoonful in a saucer and burn in the patient's room; or:

℞.	Stramonii flores. .....℥i	30
	Pulv. niter .....℥ss	15

M. Sig.: Small amount to be placed on a plate and burned.

Amyl nitrite, potassium nitrite and nitroglycerin have been used with some success in relieving the attack of epilepsy.

Chorea.

D. H. Crawford, in *Cleve. Med. and Surg. Rep.*, recommends, in the treatment of chorea, that the child be taken from school and be protected from all exciting influences that would aggravate the functional derangement of the nervous system. Mild exercise is beneficial and plenty of fresh air. In the graver cases the patient should be put to bed and placed on a good nutritious diet. He recommends cod-liver oil, milk, eggs and vegetables. Meat should be prohibited. Massage is of service in chronic cases. The author states he has derived the best results, in a medicinal way, from agaracin.

However, he has used with advantage, arsenic, stramonium, hyoscyamus and belladonna. The latter preparation is indicated where there are conditions of great mental excitement, and in the delirium approaching a maniacal state.

Bjorkman, in *Merck's Archives*, states that where rheumatic symptoms accompany the chorea and acute endocarditis is not present, excellent results may be obtained by the following:

℞.	Sodii salicyl. 3iiss	10
	Syr. rubi idaei.....℥iss	50
	Aq. destil. q. s. ad.....℥viii	240

M. Sig.: One dessertspoonful five times daily the first day; four dessertspoonfuls the second day, and three the next, etc. The foregoing dose is for a child five years of age.

Besides the administration of arsenic in the form of Fowler's solution, which the author ranks first among medicinal agents, he states that the digestive tract demands especial attention. Purgatives should be used freely, either castor oil or salines. As an intestinal antiseptic salol is recommended in 2 to 5 grain (.12-.30) doses.

Iron is of value combined with arsenic as follows:

℞.	Liq. potassii arsenitis 3i	4
	Syr. ferri iodidi .....℥i	30

M. Sig.: Ten to thirty drops in water three times a day, gradually increasing the dose; or:

℞.	Tinct. ferri chloridi 3vi	24
	Liq. potassii arsenitis .....m. lxxx	5 30

M. Sig.: Twelve to twenty drops after meals, well diluted.

Hammond recommends the bromid of zinc as follows:

℞.	Zinci bromidi 3i	4
	Syr. simplicis .....℥i	30

M. Sig.: Ten drops three times a day, increased as rapidly as the stomach can bear it.

Following combination has been employed with good results:

℞.	Zinci valerianatis	
	Ext. hyoscyami	
	Bismuthi subnit., āā.....gr. xv	1

M. Ft. cap. No. xxv. Sig.: Three to six capsules daily.

Or a combination of arsenic and chloral as follows:

℞.	Liq. pot. arsenitis .....m. iii	20
	Chloralis hydratis .....gr. v	30
	Aq. menth. pip. q. s. ad.....3i	4

M. Sig.: At one dose, to be repeated after each meal.

Medicolegal.

Privilege in Suicide Case and When No Doctor Wanted.—The New York case of Meyer vs. Supreme Lodge, Knights of Pythias, was brought to recover on a fraternal mutual benefit certificate. The defense was that the insured had committed suicide, which, by the terms of the certificate, rendered it null and void. To aid in establishing this defense, it was sought to introduce the testimony of three physicians who attended the insured, as to declarations concerning the cause of his death, made by him in their presence. One of the physicians was summoned to attend him in one of the rooms of a hotel; one was the house physician of a hospital who examined and treated him after he had been removed there; and the other was the junior surgeon of the hospital, who had assisted the house physician in the examination and treatment of the case. There was no evidence that the insured employed any one of these physicians, but, the Second Appellate Division of the Supreme Court of New York says, it was none the less true that they attended him in no other than a professional capacity. And thus was raised the question whether Sections 834 and 836 of the New York Code of Civil Procedure relate to cases where physicians professionally attend a patient who does not voluntarily require their services. Section 834 forbids any physician

"to disclose any information which he acquired in attending a patient, in a professional capacity, and which was necessary to enable him to act in that capacity." The language, the court says, is broad enough to cover cases of medical attendance, whether such attendance results from the voluntary call of the patient on a physician or from the exigencies of the patient's situation. If the relation is that of a physician attending a patient in a professional capacity, no matter how the relation was brought about, the sections apply. Section 836 provides that Section 834 applies to any examination of the physician, "unless the provisions thereof are expressly waived on the trial or examination . . . by the patient. . . . But a physician . . . may, on a trial or examination, disclose any information as to the mental or physical condition of a patient who is deceased, which he acquired in attending such patients professionally, except confidential communications and such facts as would tend to disgrace the memory of the patient, when the provisions of Section 834 have been expressly waived on such trial or examination by the personal representatives of the deceased patient." The record, the court says, showed that the party suing did not waive the privilege either on the trial or examination of any of the physicians; and even where the personal representatives waive the privilege, the physician is forbidden to disclose any fact which would tend to disgrace the memory of the patient. It could hardly be said that a declaration of the insured that he had attempted suicide would not tend to disgrace his memory. Wherefore, the court holds that there was no error in the exclusion of the testimony in question.

Dying Declarations and Privilege in Abortion Case.—The Supreme Court of Indiana says, in Seifert vs. State, that it was not disputed that dying declarations are competent in prosecutions for causing death by criminal abortions, the element of death being a substantive part of the charge. Such declarations are admitted on the ground of necessity. The necessity, however, does not depend on the stress of the particular case, but on the fact that ordinarily there is no other equally satisfactory proof of the circumstances connected with the fatal injury. Dying declarations being an exception to the rule excluding hearsay testimony, the above consideration marks, in a general way, the extent of the exception. The theory of the state in this case was that the accused furnished the deceased with a catheter, and incited her to use it to produce a criminal abortion. The court can not consent to the view that the dying declarations must be confined to the time when the deceased committed the act that resulted in an abortion, for that would leave the accused out of view entirely. The furnishing of the instrument and the inciting of the deceased to commit an abortion were as central and vital elements in the case as was the act of the deceased. In holding that declarations concerning all of these elements were proper, the court thinks that it is fully within the rule that the circumstances of the death must be the subject of the dying declaration. The statements of the deceased in her dying declarations were open to contradiction; and on the trial of the case the accused sought to contradict the portions of the dying declarations that incriminated him by the testimony of a physician as to statements that the deceased had made to him. Now, it is provided by the Indiana statute that "the following persons shall not be competent witnesses: . . . Fourth. Physicians as to matter communicated to them as such by patients in the course of their professional business or advice given in such cases." But the court thinks that, notwithstanding the broad language of the enactment, a request to a physician to commit a crime is not privileged. In this case, the matter of difficulty was the segregation of competent from incompetent evidence of the physician. If the deceased requested the physician to commit a criminal abortion on her person, as the offer to prove tended to show, that fact could have been developed, the court says, as a proper introductory fact, and that would have furnished the basis for a showing in a negative way that the proper subject on which professional advice had been sought had no relation to an abortion, and was no longer under discussion. This being shown, it would prima facie appear that the balance of the conversation was not privileged. The statute under consideration is highly beneficent in its operation, and it should not be frittered away by permitting the answering of questions which tend to reveal that which should be kept inviolate. All doubtful points must be solved against the competency of the proposed testimony, but if counsel, by a line of questions, can develop the isolated point, concerning which the court can say, this is competent, and at the same time avoid the disclosure of that which should be kept sacred, it is his privilege to pursue that course. Where, after the deceased had, in a measure, recovered from the illness occasioned by the abortion, the same physician who had performed proper professional service in an effort to relieve her from the consequences of such abortion called upon her to collect the amount of his bill, the court thinks that it would be a perversion of the statute to hold that a statement then made to him that the accused had nothing to do with her condition and would not pay a dollar was privileged.

5 *A New Method of Treatment for Chronic Anterior Urethritis and for the Declining Stage of Acute Urethritis. William W. Townsend.
6 Man's Responsibility in Sterile Marriages. W. H. Prioleau.

1. **Sudden Death in Early Life.**—Griffith reviews the causes of sudden death which may occur in children, with special reference to the effect of the thymus in producing these accidents. It was very early observed that the thymus was often enlarged in such cases of sudden death and the mechanical theory has often been given as an explanation. The author reviews the theories, showing the difficulties of the mechanical theory, the comparatively small circulation of the gland, the fact that sudden death may occur without its enlargement, etc. As regards the possible hyperthymization of the blood or some other form of autointoxication arising from a hyperplastic gland, as suggested by Escherich, he finds no clinical evidence whatever for its support, but one fact does stand out, that there is a certain constitutional anomaly seen in some children, and even in adults, which predisposes to sudden death from trivial causes. Whether enlargement of the thymus or other lymphatic tissues is coexistent is uncertain. The disturbance depends on a state of faulty nutrition, some fault of the metabolism, attended by pathologic disturbance of the nervous centers, causing extreme irritability, involving the nervous supply of the heart and respiration. The final sudden exitus appears, however, not to be due to spasm of the larynx, though it may appear to be so, but to a sudden cardiac paralysis. In the cases he gives the heart ceased to beat at the beginning of the attack. There may be, however, a central involvement of respiration occurring and ending fatally. Other causes of sudden death are convulsions, hyperpyrexia in various diseases, congenital syphilis, rupture of caseous glands or abscesses and various malformations.

2. See abstract in THE JOURNAL, xl, p. 1594.

3. **The Pancreas.**—Opie describes the anatomy of the pancreas and its anomalies. He explains the aberrant pancreatic glands, not by the presence of accessory embryonic structures necessarily, but, as in the case he reports, by entanglement of a lateral branch of the pancreatic duct in mesoblastic layers. It is, by longitudinal growth of the intestine, transported a variable distance from the pancreas, and a new duct forms in much the same way that pancreatic ducts are regenerated after section. He insists on two anatomic peculiarities which do not receive the attention that they deserve. One is that the organ consists of two functionally diverse elements on the

one hand, cells which supply to the intestine important digestive ferments, and on the other hand, cells having no communication with the ducts of the gland, but in intimate relation to the blood vessels. The other is that the close anatomic relation of the pancreatic duct to the common bile duct favors the transmission of morbid processes from the liver and bile passages to the pancreas.

5. **Urethritis.**—The method of treatment described by Townsend consists in the use of a perforated glass rod bent at right angles with a double canal, one running through from the proximal end to the air chamber at its distal termination and another above it backward from the latter to an outlet near the point of flexure. The distal end of the air chamber is open, excepting when it is closed by the urethral walls. A powder insufflated into the tube passes through the lower canal to the air chamber and is distributed on the urethral wall at this point. As the powder is forced into the insufflator the tube is gradually withdrawn and the mucous membrane of the urethra is consequently covered. It is readily sterilized by boiling and drying in an alcohol flame when the water has been entirely shaken out. He uses astringent and antiseptic drugs, aristol prior to applying an astringent, if there is much pus accumulation. In his experience zinc, copper and aristol have accomplished the desired effects. He uses three or four treatments a week. He recommends this method in chronic anterior urethritis and the declining stages of the acute disorder, but never in the early stages of the condition.

7 *Infantile Insanity in Its Relation to Moral Perversion and Crime. Allan McLane Hamilton.
8 *Gastric and Intestinal Crises. C. A. Ewald.
9 *Intravenous Infusion in Puerperal Septicemia. Edward Waltzfelder.
10 *The Correlation of Alcoilsm, Crime and Insanity. C. A. Drew.
11 The Medical Officer of the United States Navy. Gilbert T. McMaster.

7. **Infantile Insanity.**—Hamilton discusses the forms of insanity that occur in children, especially those with criminal tendencies, illustrating them by various examples, such as the Jesse Pomeroy case and others. He thinks an error is made in considering children's weaknesses that are not insanity as responsible crime and suffering them to be sent to penal institutions and idiot asylums when they might be properly guided and educated out of their tendencies. The hope for relief is in correctional institutions where children are not stamped as young felons, such as farms and trade schools, training ships and so on. He thinks the government regulation of newspapers and injurious publications should be brought about, as they are largely influential in producing juvenile criminality.

8. **Gastric and Intestinal Crises.**—Ewald first notices the well-known gastric crises of tabes and also describes some conditions occurring independently of tabetic disease, but closely resembling those due to this cause. There may be nothing typical about the time of these attacks, or they may present a peculiar type of their own, recurring with regularity at rare intervals. There are no specific signs present pointing to a disease of the spinal cord, but neurasthenic or hysterical symptoms are usually prominent. These attacks are generally brought about by the partaking of food, and it frequently happens that the same articles of food may precipitate an attack at one time and not at another. The so-called idiopathic crises, moreover, may be influenced therapeutically, which is hardly ever the case with true tabetic crises. He points out how errors of diagnosis may lead to useless operations for lesions which do not exist. In cases due to disease of the central nervous system not much can be done; there is no way of cutting short the attack. Suggestion may have considerable influence in some cases, but reliable treatment is wanting. In grave cases he makes use of morphin. In the beginning it is possible to check the attack with small doses, but they will have to be increased later. There is danger of making morphinomaniacs. The method of Corning, recently tried by Chatelin, injecting local anesthetics into the epidural space of the spinal cord from the sacrum, seems to have some good effects. Technically the process is simple and easy. Cases of periodic vomiting due to functional neuroses, i. e., idiopathic vomiting, are much more satisfactory than those of gastric and other crises due to organic changes in the central nervous system. General tonic treatment by hygienic and dietetic measures, irrigations of the stomach with soothing or slightly astringent solutions, sedatives, such as the bromides, hyoscyamus, etc., and if vomiting is of reflex origin, painting the nasal mucous membrane with cocain are usually of value.

9. **Puerperal Septicemia.**—Two cases of puerperal septicemia treated by intravenous infusions of decinormal salt solution with good results are reported by Waitzfelder. In one case formalin infusions were first used, but after forty-eight hours another injection was required and decinormal solution was given with perfectly identical results.

10. **Alcohol in Crime and Insanity.**—Drew finds that in 154 cases admitted in two years to the Massachusetts State Asylum for Insane Criminals, 11, or 7 per cent., claimed never to have used alcohol as a beverage. Of these 11, 3 were epileptics and 2 were well-marked cases of imbecility. Ninety-six, or 62 per cent., were hard drinkers. The remaining 31 per cent. considered themselves only moderate drinkers, or were too demented to tell, or for personal reasons refused to give information. Fifty-six, or 36 per cent., acknowledged intemperate fathers, while 21, or less than 14 per cent., acknowledged intemperate mothers. In the 4,437 admissions to the other five state hospitals the cause of insanity in 14.88 per cent. was given as intemperance. These statistics, however, are not altogether reliable, as there is a great tendency to withhold facts. In the Worcester Asylum a careful investigation seemed to show that alcohol was the sufficient cause of insanity in 21 per cent. of the men and 7 per cent. of the women, and a causal factor in about 10 per cent. of the women and 32 per cent. of the men. Poverty, overwork, stress, worry, blighted hopes and consequent ill health following inebriety are not credited to alcohol in these statistics. If these so-called moral and mental causes were traced back the proportion of insanity charged to alcoholism might be much more equal between men and women.

12 *The Need of an Institution for the Education of Nurses Independent of the Hospitals. Francis P. Denny.
13 *Hemostasis by Compression and Heat. John W. Keefe.
14 *Polioencephalomyelitis and Allied Conditions. (Concluded.) E. W. Taylor.
15 A Case of Paget's Disease of the Nipple Treated by the X-Ray. Edith R. Meek.

12. **Trained Nurses.**—Denny pleads for the education of nurses, in part at least, outside of the hospital. The theoretical work and whatever requires study can not be accomplished on account of the pressure of duties. He would have an institution to give the preliminary course of instruction, and a single plant—the same corps of teachers, the same lecture rooms and laboratories—could provide for a number of different hospitals.

13. **Hemostasis.**—Keefe reports cases in addition to those in a former article published in the *Boston Medical and Surgical Journal* of January 8, of the use of Downes' electrothermic angiotribe, which he considers of decided practical value. No secondary hemorrhage is reported to have taken place. The most interesting case was one of resection of 14 inches of the intestine in a man, showing the ease with which the bowel can be resected. The perfect asepsis, he says, is certain to eliminate the mechanical appliances now in use for this purpose. The wide range of usefulness of this instrument renders a surgical outfit incomplete without it. The advantages claimed for the electrothermic angiotribe are: the exclusion of the ligature; hemostasis *en masse* or of isolated blood vessels; aseptic gastrectomy, gastro-enterostomy and resection of intestine; appendectomy; salpingectomy; extrusion of septic material during operation being rendered impossible; sterile occlusion of the Fallopian tube; absence of irritable and painful stumps; less tendency to post-operative adhesions; rapidity of operation; no secondary hemorrhage from slipping of ligatures, or suppurating sinuses due to ligatures; less pain subsequent to operation, and there is no puckering or

dragging on the tissues; value in removal of cancer as there can be no danger of inoculation with cancerous material during the operation, and the heat destroys the cancer cells beyond the point of application of the clamps.

14. **Poliencephalomyelitis.**—In the concluding instalment of his article Taylor offers the following conclusions, which he considers legitimate:

That a large group of affections of the central nervous system exists, provisionally to be regarded as inflammatory, in which may be included encephalitis, poliencephalitis, superior and inferior, poliencephalomyelitis, poliomyelitis, encephalomyelitis and, with reservations, Landry's paralysis, and possibly myasthenia gravis, and certain apparent peripheral nerve infections.

That these affections should be regarded as essentially identical, differing only in symptomatic expression.

That the evidence for this lies in the simultaneous involvement in individual cases of various portions of the nervous system, a notable example of which is given in poliencephalomyelitis.

That we should gain in our understanding of these and various other affections of the nervous system if we adopted a classification based on pathologic alterations and on etiology, wherever possible, rather than on clinical symptoms determined by anatomic subdivisions.

That, admitting a somewhat definite pathologic alteration of the nature of inflammation, as a fairly constant factor, we may assume the existence of a common exciting, probably toxic, cause.

That the nature of this cause is practically unknown, that its manifestations are not always uniform and that our final understanding of the distribution and prognosis of these affections must depend, first, on our knowledge of these exciting causes, and, second, on the nature of individual susceptibility and resistance.

19 *A Contribution to the Pathology and Prognosis of the Diseases of the Bladder. Robert Holmes Greene and Harlow Brooks.
20 Impressions of the Non-heredity of Acquired Characters. A Rejoinder. Lawrence Irwell.

16. **Public Toilets.**—Williams pleads for the establishment in American cities of public conveniences such as exist in London, Paris and elsewhere and illustrates his article with pictures of such as are in use abroad.

17. **Tabes.**—The pathology of tabes is discussed at length by Collins, who thinks that evidence tends to show that the essential lesion is in the elective progressive degeneration, segmentary in type (in contradistinction to Wallerian), of the posterior columns of the spinal cord. The distribution of the degeneration corresponds with the intraspinal distribution of the posterior root-fibers. After the degenerative process has existed for an indefinite time in the cord, the endogenous fibers of the posterior columns are involved. This changes the anatomic picture and the confines of the pathologic process. In most cases of tabes of long duration pathologic alterations have been found in other portions of the nervous system. He would therefore adopt the theory of Marie and Guillain and hold that the lesions of tabes are the results of the activity of a poison, generated by syphilis, acting primarily on the intramedullary distribution of the posterior roots.

19. **Diseases of the Bladder.**—The following are the conclusions of Greene and Brooks' article:

1. The most frequent cause of diseases of the bladder is: (*a*) Lesions of the central nervous system, causing dilation, (*b*) septic processes of various varieties, (*c*) hypertrophy of the prostate.

2. In all conditions in which the spinal cord or central nervous system is involved, frequent and early catheterizations should be resorted to, to prevent the bad effects of overdistention or the possibility of cystic rupture.

3. Conditions of the bladder must greatly modify the prognosis in operative procedures for the relief of obstructions of the urinary flow, therefore the importance of cystoscopic and other examinations can not be too strongly insisted on.

4. Hypertrophy of the bladder wall is due to four different processes, separate or combined: (*a*) Inflammatory infiltration, (*b*) increase of the fibrous connected tissue, (*c*) smooth muscle hyperplasia, (*d*) infiltration by new growth. The clinical symptoms in hypertrophy of the bladder depend on which of these factors predominate.

25 Pertussis with Unusual Cerebral Symptoms. Edwin E. Graham.

21. **A New Plastic Operation.**—Senn describes the manufacture of a face in a case where a large portion of the normal face had been eaten away by a caustic application. It was made by the transfer of about one-half the scalp down over the face and the results were an improvement. Thirteen different operations were required to complete the work.

22. **Whooping Cough.**—In the treatment of whooping cough, Kilmer recommends the wearing of an elastic belt over the abdomen or thorax, or both, as the case may be, to control the tendency to vomiting, combined with the alternate use of antipyrin with the bromids and quinin, as recommended by Kerley. He holds that whooping cough is a self-limited disease and runs its course in the same way as pneumonia, but that these methods are palliative and curative as far as any methods that have been employed.

34 *Puerperal Eclampsia. A Plea for Treatment with Veratrum Viride. J. S. Hammond.
35 Contribution to Renal Pathology and Etiology. Henry Jacobson.

34. **Eclampsia.**—Hammond advocates veratrum as a drug *par excellence* in puerperal eclampsia, both on account of its action on the circulation and arterial tension and as a spinal depressant agent and obtunder of the nervous centers generally. The emesis it provokes helps in elimination and excites the excretion of bile. It also eliminates by diaphoresis. It is not contraindicated in any form of kidney disease, and it is much safer than chloral, which is not eliminative. He holds that it has not been given a fair trial by obstetricians. It should be given in doses to reduce the pulse to sixty or below and hold it there.

40 Congenital Syphilis in the New-born and Young Infants. Mary Strong.
41 The Syphilitic Affections of the Eye. H. B. Lemere.
42 The Microscope in the Practice of Medicine. W. Francis Mitchell.

36. **Hereditary Syphilis.**—Moore, from the facts as far as known, concludes that the father can infect the embryo through the spermatozoa and the mother at the time of conception through the unimpregnated ovum. Moreover, if she contracts syphilis within the first seven months of pregnancy she is liable to infect the fetus. As regards marriage, syphilis is not transmissible after four to seven years without treatment and with treatment, after three and one-half to four years after the disappearance of secondary symptoms, to which must be added six months without treatment and without symptoms. He would authorize marriage after these periods. In inherited syphilis in a child the condition will depend on the severity of the disease in the parents, being more severe when both are infected than when only one is. The more recent the disease in parent the more severe in the child. Specific treatment of the parents has an effect on the grade of the symptoms in the fetus. A large proportion of children of syphilitic parents are defective, about one-third are stillborn and abortions are frequent.

37. **Syphilitic Immunity.**—From a study of the subject and from correspondence, Stokes concludes that second infection may occur in syphilis about as often as in smallpox or measles,

say once in 2,500 cases. He finds no case on record where it occurred in less than two years after the appearance of the secondary symptoms of the first attack. Usually the immunity lasts for life. Colles' and Profeta's laws are no exception to Ehrlich's hypothesis of immunity. The second infection is more frequent in hereditary than in acquired syphilis.

51 Remarks on Primary Neurotic Atrophy (Charcot-Marie-Hoffman Type), with Report of a Case in Which There Was Excessive Indulgence in Tea and Coffee. Alfred Gordon.

48. **Tabes and Muscular Atrophy.**—Collins reports cases where tabes was complicated with muscular atrophy and studies the pathology. The first case was one of tabes with atrophy of neural origin, the lesions of the peripheral nerves being a degenerative neuritis. The tabes was not typical. The second case had been called syringomyelia by certain persons referring to it, a diagnosis for which the author sees no grounds. He thinks the most legitimate interpretation to be put on it is that the cause of the atrophy was a multiple neuritis probably of alcoholic origin. The third case showed apparently no symptoms of tabes until a careful examination revealed them. The muscular atrophy might either be dependent on a peripheral lesion, such as a neuritis, or due to a thrombosis of the cornual branch of the anterior spinal artery. He notices some cases reported by others.

49. **The Achilles-Jerk and the Front-Tap.**—The conclusions reached by Walton and Paul are that the Achilles-jerk is as constant in health as the knee-jerk, and varies less and is the most easily elicited and uniform of all tendon reflexes. It usually disappears early in tabes and is as diagnostic as the knee-jerk. The enfeeblement of the latter on one side or both may be due to prior toxic influence, as diphtheria. This may also be true of the Achilles-jerk. The front tap, which is made by tapping the tibialis anticus while the foot is flexed dorsally, thus producing plantar tension, is generally present bilaterally and in about 40 per cent. of normal individuals, in some very active. Its presence alone does not establish disease or indicate excessive irritability. In organic disease it is generally increased with the other reflexes in hypertonic, and decreased in hypotonic states. He has found it present in about 71 per cent. of cases of functional neuroses and in 75 per cent. of epileptics. Both of these reflexes deserve to be put on the list of routine tests for purposes of diagnosis, but this is particularly true of the Achilles reflex.

59 *A Contribution to the Chemical Pathology of Acromegaly. David L. Edsall and Caspar W. Miller.
60 Karyokinesis in the Macroblast. C. Y. White.

52. **Regeneration of the Posterior Spinal Roots.**—Spiller and Frazier have experimented on dogs, performing laminectomy and exposing and dividing the posterior roots of three spinal segments about 1.5 cm. from their point of entrance into the dura; the divided ends of the lowermost three were brought into apposition by a silk suture. The other two remained in apposition without any artificial means. In the only successful case the dog was killed ten months after operation and the spinal cord removed and studied microscopically. They found the intramedullary portions of the roots operated on entirely degenerated and no young nerve fibers anywhere in the usual distribution of the posterior roots within the cord. The conditions for regeneration were made as favorable as possible, but it did not occur. They think their experiment is rather conclusive, though they regret that more animals did not survive to corroborate the results.

53. **Spring Catarrh.**—A case of this disease is reported by de Schweinitz and Shumway with microscopic examination of the excised tissue of the growths from the superior tarsal conjunctiva. Their findings correspond with the description of the growths by Vetsch, Horner, Uhthoff, Knies, Taylor, Schoebl, Haab and Fuchs. Neither epithelium nor connective tissue elements especially predominated in the specimens, as each constituted a definite portion of the new growth.

59. **Acromegaly.**—Edsall and Miller have experimented on the nutrition and elimination of two cases of acromegaly, giving reports in detail. Their findings seem to show that there is in acromegaly a growth of abnormal bone rather than an abnormal growth of bone, and that there are very marked abnormalities in the soft tissues as well as the bones. The alteration in the bone is the result of metabolic abnormalities rather than a mere tendency to distorted overgrowth.

61 *A Further Investigation of the Milk Supply of Baltimore, with Especial Reference to Its Suitability for Infant Feeding. Edwin H. Schorer and Victor H. Bassett.
62 Some Remarks on a New Modification of the Bottini Operation. W. B. Wolf.
63 Method of Instruction in Surgical Pathology. J. C. Bloodgood.

61. **The Milk Supply of Baltimore.**—Schorer and Bassett have investigated the milk supply of Baltimore, both at the dairies and retailers, and find that it is very generally adulterated by water and that preservatives are so common that a large proportion of the milk sold should be considered unsuitable for infant feeding. Adulteration, they think, occurs largely in the hands of retailers. The bacterial count and acidity test are satisfactory means of determining the suitability of milk for infant feeding and are of greater value than the ordinary physical and chemical tests. The standard proposed by Park, that of 500,000 bacteria per c.c. at the receiving stations and 1,000,000 in milk offered for sale, are practicable standards for Baltimore, and can be met by moderate care in the production of milk, and refrigeration later. With slightly improved conditions a number of the better dairies could supply milk which could be certified and contain less than 100,000 bacteria per c.c.

65 *Relief of Bladder Symptoms by Treatment of the Uterus, and Vice Versa. H. S. Crossen.
66 The Value of the Static Machine as a Therapeutic Agent. H. N. Chapman.
67 The Relation of Modern Researches on Immunity to Physiology. John Zahorsky.

65. **Bladder Symptoms and the Uterus.**—Crossen reports a case of uterine disorder with various symptoms associated with it, including bladder disturbance, and this seemed to be the principal difficulty. It was treated with poor success for a number of years. He operated, opening the posterior cul-de-sac, and loosened up the uterus from adhesions. He then performed the Alexander operation, with the result of completely curing the bladder difficulty and all the other symptoms. In another case there was incontinence of urine, due to destruction of the urethra by a syphilitic ulcer, unrelieved by operation. In studying the case he concluded that the failure was due to dragging of the displaced uterus on the neck of the bladder and the irritation of the catheter in the wound, so he opened the abdomen, broke up the adhesions, attached the

fundus uteri to the abdominal wall and then repaired the pelvic floor. When the patient had recovered he then operated a second time directly to relieve the uterine incontinence. The result was perfect, which he attributes largely to the uterine operation. In still a third case there were symptoms attributed to injury of the pelvic floor with downward displacement of the uterus, which were cured by washing the bladder out with boric acid solution.

74 Notes on the Treatment of Puerperal Infections. Thomas J. Watkins.
75 Brometone. E. Fletcher Ingals.

68. See abstract in THE JOURNAL, xl, p. 1304.

69. **Foods.**—Wesener describes the process of digestion and goes at length into the question of adulteration, showing that a large proportion of the articles of food in daily use are more or less sophisticated. The finer qualities of flour are an exception; it is rare to find them adulterated. Among the food substances that are absolutely pure he includes flour, cereals, meat and fresh vegetables. Of all the food preservatives used formalin is the most harmful as acting directly as an irritant on the gastrointestinal tract, making the proteids of milk and other substances in which it is used indigestible. The arrangement of a well-balanced diet is a complex matter and largely varies with individuals. The tendency to overeat is especially condemned.

71. **Iodophilia.**—Gehrmann reviews the subject of the iodin reaction on the part of the white cells, which is most constantly found in connection with suppuration, diabetes and severe anemia. He is inclined to think that iodin-staining substances are of the nature of glycogen rather than amyloid. The test should be more generally employed.

Albany Medical Annals.

June.

76 *The Prevention of Puerperal Eclampsia. John T. Wheeler.
77 *Report of a Case of Tetanus Treated with Antitetanic Serum. Charles B. Mallery.

76. **Puerperal Eclampsia.**—The importance of frequent examinations of the urine in pregnant women is insisted on by Wheeler, who believes that women themselves should be taught to make examinations, and if any warning symptoms occur for the physician to carry them on. He always teaches his patients to make the test if they reside at a distance or are poor or there is anything that prevents close personal attention.

77. **Tetanus.**—Mallery reports a case of tetanus successfully treated with antitetanic serum, and he has looked up the literature on the matter. He finds 277 cases thus treated with a general mortality of 63 per cent., and as compared with the cases treated without antitetanic serum the value of the method is made evident. The small mortality of the St. Louis outbreak from infected diphtheria antitoxin is attributed by Fisch to the preventive use of the serum. He concludes that his own case would have been fatal without this treatment. The condition was desperate when it was begun, and was at least arrested by 40 c.c. of the antitoxin. The effect of the serum treatment was also noticeable in the speed of recovery. Reports show that favorable cases treated in other ways recover slowly and that muscular rigidity, and especially trismus, continues for weeks and months. Had he been able to give the serum in larger quantities at first and dared to use it as he did later, he believes that he could have cured the patient much quicker. He also doubts whether there is any notable difference as to the method of injecting, whether it is put under the skin by subcutaneous injection or into the spinal canal, the vital point being the early use of the remedy in large quantities. In his case he used 400 c.c., or 20,000,000 units, injecting it indiscriminately under the skin of the legs, arms, chest or abdomen.

Archives of Pediatrics, New York.

79 The Changes in the Management of Laryngeal Diptheria Treated by Intubation. Edwin Rosenthal.
80 *The Paroxysms of Whooping Cough Treated by Pulling the Lower Jaw Downward and Forward (Naegeli). Jacob Sobel.
81 Congenital Asymmetry or Hemihypertrophy in an Infant. A. Hymanson.
82 A Case of Ludwig's Angina from Infection of the Lingual Frenum. Charles J. Aldrich.

80. **Whooping Cough.**—Sobel finds, as a result of his experience with the Naegeli maneuver for overcoming whooping cough, that: "1. Pulling the lower jaw downward and forward controls the paroxysms of whooping cough in most instances, and most of the time. 2. The method is usually more successful in older children than in younger ones and infants. 3. In cases without a whoop the expiratory spasm, with its asphyxia, is generally overcome, and in those with a whoop the latter is prevented. 4. As a single therapeutic measure for the control of the paroxysms it deserves a place in the treatment of pertussis and is as successful as any single drug, or even more so. 5. Mothers, nurses and other attendants should be instructed in its use in order that the oncoming attacks, especially at night, might be arrested. 6. The manipulation is harmless, painless and easy of application, without any of the ill effects of drugs; it offers a maximum good effect with a minimum derangement. 7. The only contraindication to its application is the presence of food in the mouth or esophagus. 8. Patients treated in this manner are less likely to suffer from complications and sequelæ than those treated only medicinally; they emerge from the disease in far better condition, less exhausted and less emaciated because vomiting has been controlled. 9. It is advisable to try the maneuver in other spasmodic coughs and laryngeal spasms (laryngismus stridulus, pressure of enlarged cervical and bronchial glands, influenza, glottis spasm in catarrhal laryngitis), although my experience has seemed to show that it is far less efficacious in these conditions than in whooping cough. 10. This method being directed mainly to the control of the glottis spasm, does not preclude the advisability of supporting and sustaining the patient, guarding his gastrointestinal tract, establishing equilibrium in the nerve centers and affording him every possible hygienic advantage. 11. It is particularly indicated in instances complicated with diffuse bronchitis, bronchopneumonia, convulsions, epistaxis, subconjunctival or subcutaneous hemorrhage, or sublingual ulceration and in those children who by virtue of age, the presence of rachitis, scrofula or general debility are predisposed to serious complications and sequelæ."

88 Ineffectual Attempt to Remove a Piece of Steel from the Eye with the Haab Magnet. William H. Wilder.
89 Incised Wound of the Cornea Made by a Fragment of Spectacle Lens. S. Mitchell.

84. **Ophthalmoscopic Examination of the Macula.**—Jackson describes the methods of studying the ophthalmoscopic appearances of the macula, and shows how it can be done with the ordinary ophthalmoscope with an undilated pupil, if the instrument is used to the best advantage. "The corneal reflex can be so reduced as to allow the surgeon to see the pupil alongside of it, by making the sight-hole small, 1.5 mm. in diameter, and holding it so that one edge of it is in front of the center of the surgeon's pupil, or by using a half mirror. The visible field can be enlarged by getting close to the patient's pupil and excluding all unnecessary light. The illumination of the retina can be rendered brilliant at a certain point, or diffused equally over the whole visible field, by adjusting the source of light at the proper distance from the mirror, and by placing the right lens in a trial frame before the patient's eye."

85. **Spring Catarrh.**—This condition was first noticed by Arlt, and subsequently by others, including Saemisch, who gave it the name. The condition is here described by Malone. He gives the symptoms and peculiar appearances. There is photophobia, stinging pain, great itching with the addition of a stringy muco-purulent secretion, interfering with vision, all aggravated by warm weather and disappearing during the winter months. On examining the eye we may find only the conjunctiva covering the tarsus involved, that is, in the tarsal variety; or, it may be limited to the conjunctiva of the ball, that is, the bulbar variety, or both may exist together. On everting the upper lid we find it covered with broad, flattened, papilliform excrescences over the tarsus and over the whole a delicate bluish-white film as if a thin layer of milk had been spread over the conjunctiva. The growths may cover the whole lid or may be few and small and less characteristic. If the bulbar conjunctiva is involved it is thickened and unequally raised at the limbus, forming pale, translucent or waxy nodules encroaching on the cornea, but extending most over the conjunctiva. They may be scattered or involve the whole circumference. He thinks it generally begins in the superior limbus, then the inferior, and both sides then become involved. It is very similar in some respects to trachoma, but is not identical in its structure, and he points out the differences, which are leucocytic and diffuse infiltration, no clearly defined nodules, as in trachoma, the different situation and the thick, resisting bands as compared with the thin and delicate ones of trachoma. He has found little good from cauterization for the tarsal type. He curetted the growths off clean and reports a cure in one case, with another greatly improved. He thinks if we can remove from the tarsal cartilage all of the diseased tissue, we may have a cure. With the bulbar variety he has had no special success. He uses salicylate of sodium, 10 gr., with cocain 2 to 5 grains to the ounce, four or five times a day as a soothing lotion.

99 Notes from the Throat Department of the Pathological Laboratory of the Manhattan Eye and Ear Hospital. Jonathan Wright.

90. **Amyotrophic Lateral Sclerosis.**—A case is reported by Collins with elaborate microscopic findings. He discusses the nature of the disorder, its starting point and pathology, its symptoms, etc. It is characterized by symptoms of progressive muscular atrophy of the Aran-Duchenne type, complicated with bulbar involvement, plus spastic paralysis, and exaggeration of tendon jerks all over the body. The morbid process consists in a decay of the peripheral motor neurons of the ventral horns, terminations of the pyramidal neurons, and atrophy of the column and the commissural cells of the gray matter. It extends centrifugally in the peripheral motor neurons, centrifugally and centripetally in the central motor neurons. The microscopic features are atrophy of the anterior horns, with disappearance or lessening of its cell constituents without vascular change, degeneration of the fundamental tracts to a greater or less extent, degeneration of the pyramidal tracts to a varying extent. The question as to which is first involved, the peripheral motor neuron or the central motor neuron, is not answered, though he is inclined to believe that one may be primarily involved in one case and the other in another. It is not necessary to have complete involvement of both systems of neurons for clinical purposes. The pyramidal columns may be uninvolved even in the typical form. Other parts of the cord that have been found involved are the posterior columns and the direct cerebellar tracts occasionally. He does not consider it a variety of spinal progressive muscular atrophy. From a study of the literature of 94 typical cases, adding 10 of his own observation, he finds a large number of etiologic factors reported. Trauma, he thinks, has but little etiologic influence. There is much to suggest infection or intoxication processes. A number of cases seem to indicate this, some following parturition, some were syphilitic. But all the factors that have been incriminated, such as injury, exposure, intoxication and the like, Collins thinks are only exciting causes. There is something back of these which is the real cause, and he thinks we should look to the pathologic chemist for the discovery of the real toxic agency in the disease.

91. **Congenital Shoulder Dislocation.**—The etiology and pathology of this disorder is indefinite, according to Cumston, no theory giving thorough satisfaction. It is difficult to explain why it should be more common in girls than in boys, and why such cases are more frequent in girls belonging to the lower classes than those of well-to-do parents. Possibly rickets has something to do with it. Heredity is an important factor to be considered. He is inclined to think that alcoholism, tuberculosis, syphilis, etc., in the ancestors are among the potent factors. The most striking pathologic lesion is arrest in the development of that portion of the skeleton on which the muscles take their insertions. The muscles themselves are atrophied. The capsule of the joint is intact, and its insertions are normal, but it is relaxed, very distended and occasionally considerably elongated. The diagnosis is discussed at length by Cumston. The question as to whether it is a case of obstetric trauma, obstetric paralysis or cerebral or syphilitic, or tubercular, etc., in nature is noticed. There is a complete absence of fever. All the muscles have their voluntary contractility immediately after birth; their atrophy is due to long disuse. In the vast majority of cases the only satisfactory treatment is surgical. He favors Duplay's incision in cases where free operation is required, otherwise the simple anterior incision of Ollier will suffice. A case is reported in detail.

93. **Exophthalmic Goiter.**—Hyde and McEwen report several cases of cutaneous disorders in connection with Graves' disease; one of hidrocystoma, one of telangiectases, one of cutaneous pruritus, one of pruritus and angioneurotic edema. These are discussed at length and especial attention called to the case of hidrocystoma, which shows that it may develop in women nowise exposed to the ordinary causes, such as moist atmosphere, etc. The authors review the literature of the cutaneous syndromes of Graves' disease and suggest that in some non-typical cases a point of interest might arise in view of the existence of the skin lesions.

94. **Epicarin.**—This substance is said to be a condensation product of creotinic or creosotinic acid and B. naphthol, and to combine the properties of creosote and naphthol. It was first brought into notice some years ago by Kaposi. It is a reddish amorphous powder with a slight odor resembling acetic acid, is soluble in alcohol, ether and liquid vaselin. Van Harlingen and Dillard have treated a number of cases of tinea circinata and tinea tonsurans with this drug, using principally a tincture of a 10 to 20 per cent. solution and offer the following conclusions:

1. In epicarin we have an important addition to the means of combating ringworm of the scalp. Used, preferably, in the form of a tincture of 10 to 20 per cent. strength and, after epilation, it appears to act more rapidly than any of the remedies heretofore employed in restoring the hairs to a normal condition. 2. In ringworm of the body the tincture seems to be irritating and slow in action. The ointment acts better, but is not equal to the ammoniated mercury ointment, nor to most of the remedies ordinarily employed. 3. In (a single case of) favus the result of the use of epicarin was such as to encourage trial. 4. In scabies, so far as our experience goes, epicarin in the form of the tincture and simple ointment is apt to prove very irritating and is by no means equal to the sulphur and naphthol nor to the other ointments ordinarily employed.

95. **Blood Pressure in Cerebral Compression.**—In summarizing his article Cushing calls attention to the following points:

Varying degrees of rapid increase in intracranial tension produce disturbances in the intracranial circulation. To these circulatory

disturbances the symptoms of compression are solely due. The condition known as acute cerebral compression may be conveniently subdivided into four stages, dependent on the degree of circulatory alteration which has been reached. Each of the stages has its own more or less characteristic symptom-complex. The major or underlying symptoms originate in the centers situated in the medulla, and are only called out when the degree of intracranial tension begins to approach the arterial tension so that anemia is threatened. A circulatory condition in the medulla which borders on anemia has the effect of stimulating the vasomotor center. Thus, a rise in blood pressure is occasioned which restores the local circulation. The extent of this rise may be taken as an indication of the degree of advancement of the compression. Beyond a certain point, however, this reaction can not take place. The vasomotor center under these circumstances fails, and the respiratory efforts cease entirely. In conjunction with other symptoms, a progressive increase in arterial pressure or a high degree of the same, which has been already reached, or a pressure which exhibits from moment to moment great alterations in level may be taken as a certain indication of the advisability of early operative intervention. In case there are localizable symptoms the site of trepanation is plainly indicated. In case of generalized compression from widespread hemorrhage when there are no localizing indications, the intracranial tension should be relieved by the elevation of a large osteoplastic flap from one hemisphere or the other, with a corresponding opening in the dura.

97. **Gangrene of the Lung.**—In the case reported by Riesman, Wood and Pfahler, the condition was desperate, and recovery apparently impossible by any means except operation. The fifth rib was resected, the gangrenous portion of the lung found immediately below the pleura and some necrotic lung tissue removed. The cavity was as large as a man's clenched fist, as found by digital examination. The parts were cleansed with gauze sponges, which brought away all loose matter. It was then packed with sterile gauze and the wound was redressed daily. While the discharge was very profuse at first, the patient gradually improved, and only a month later was in a fair condition, the cavity decreasing in size. From that time on recovery was rapid and satisfactory. The authors discuss the condition and its treatment, insisting on the importance of definitely locating the trouble, using skiagraphs if necessary, making ample opening in the pleura and rib resection, securing adhesions to the pleura before entering the lung, and if they do not exist, stitching the two layers together around the proposed opening into the lung, which may be made in forty-eight hours or sooner if the patient's condition demands it. The condition seems to follow lobar pneumonia in most cases. They particularly emphasize the absence of fever in the case; the temperature was normal before operation and only rose to about 102 or 103 after the resection for a day or so. Another point mentioned particularly is the gangrenous smelling sputum and the absence of elastic tissue. The value of the *x*-ray in diagnosis is emphasized, and they remark that the acute form is more favorable in its prognosis than the chronic. The mortality without operation is necessarily very high, 70 or 80 per cent. Under operative treatment a death rate of 34 per cent., according to Garré and Sultan, is about normal. In some cases physical examination and examination with the *x*-ray after operation showed a normal lung where there had previously been a gangrenous cavity. The second radiograph in this case also showed a restored lung. Whether there is a true hyperplasia of the air passages or merely an enlargement of the existing ones, can not be said. The importance of adhesions is also emphasized.

98. **Zomotherapy in Tuberculosis.**—From experiments made on dogs in the treatment of tuberculosis, Brown concludes that raw meat has no perceptible effect on the duration of experimental tuberculosis in dogs if the bacilli are virulent and a sufficient number injected intravenously; that it has no effect on the prolongation of the duration of experimental tuberculosis in dogs, even if the bacilli are attenuated, provided a sufficient quantity is injected; that under the same conditions dogs fed on a mixed diet with no raw meat may live a much longer time. As regards the use of meat in pulmonary tuberculosis, he says that it is highly essential in the dietetic treatment and that the judicious mixture of carbohydrates, fats, etc., is essential to the treatment. Raw meat is better than meat well cooked. Meat juice is of great value in suralimentation. It can be taken when the patient can take no other form of meat. The juice from raw meat seems slightly if at all better than the juice from meats slightly browned. The disadvantages of preparing and preserving raw meat juice more than offset its advantages. Patients who object to juice from raw meat will willingly take that from meat browned. It is of value as it can be administered in the form of jellies, ices, etc.

5 *Beneficial Results of Gastro-enterostomy in Some Cases of Irremovable Carcinoma of the Stomach, in Which the Pylorus is Not Obstructed. Bilton Pollard.
6 Case of Hypertrophic Pulmonary Osteoarthropathy. Sydney W. Curl.

1. **Muscular Movements.**—This first lecture of Beevor's is given over to a discussion of muscular movements of the fingers and hands, and is too detailed for abstracting.

2. **Cancer of the Rectum.**—Cheyne discusses the treatment of cancer of the rectum, more especially the radical treatment. The majority of surgeons agree as to the value of operation in suitable cases. Two questions arise: First, the value of operation; secondly, the risks it involves. In the majority of cases of rectal cancer the growth is slower than in most other places. Therefore, there is nothing inherent in the morbid processes that opposes radical operation, nor is there anything in the condition which makes it specially difficult in suitable cases. The rectum is comparatively accessible from below, and the whole of it can be reached by the combined abdominal and perineal route. Moreover, the lymphatic glands run in close contact with the intestinal wall, and if operation is done sufficiently early, when the glands are not too much affected, there is a very fair percentage of recoveries as compared with cancer elsewhere after operation in suitable cases. The proportion, however, of suitable cases is somewhat less than in cancer of the breasts or extremities. Cheyne estimates that only about 20 per cent. of the cases that present themselves to the surgeon will be fit for radical operation, with a view to the complete removal of the disease, though this percentage may be somewhat increased by recent improved methods. However, aside from complete recovery, operation may prolong life and save the patient a great amount of suffering. As regards mortality, it is no doubt higher than that after operations through unbroken skin, such as amputations, excision of the breast, etc., though in such cases the mortality is exceedingly slight. The question as to what are suitable cases is answered by him as follows: Operation should be undertaken only when the patient is in a fair state of health and likely to stand operation and prolonged convalescence; in those who are not suffering from organic disease or where there is no evidence of extension to other parts of the body. The chief local contraindication is a fixed bowel, which means that the growth has penetrated the intestinal wall and begun to probe into the surrounding tissue. In case of tumor situated low down and adherent to the posterior vaginal wall, there is a possibility of good results. Another point which has been considered a contraindication is the situation of the cancer. He thinks the dictum has been a little too decided on this point when it is said that a cancer that can not be reached by the finger to its upper limit is inoperable. By opening the abdomen and keeping the intestines well out of the way the bowel can be divided above the cancer, and if it can not be united with the rectal extremity, it can be brought out at a colotomy wound. The question of primary colotomy is discussed. He thinks it should be an exceptional procedure rather than the general rule. As to the methods of gaining access to the disease, the perineal and vaginal routes are the suitable ones where the disease is quite low down. The sacral and abdominal or combined abdominal and perineal where the disease is high up. In the majority of cases the sacral route is preferable. As regards the combined abdominal and perineal operation as done by Quénu, it is on trial. So far its mortality has been considerable. Cheyne prefers personally to remove the affected portion of the intestine above a clamp; then invaginate and stitch up the lower end of the bowel and leave it in position while the other end is brought out in the groin and the ligature—which has been applied around the bowel before the removal of the disease—left *in situ* for two or three days if possible. There is no special advantage in dissecting out the lower end of the rectum. To avoid sepsis he cautions against infecting the hands, and besides disinfecting the perineum, he also stitches up the anus tightly to prevent any escape of matter during the course of the operation. Moreover, when possible, he peels down the glands and ligates the bowel in two places, the ligatures being left long, and brings the rectum as far as possible outside the wound before the bowel is divided. He also generally employs a prophylactic injection of antistreptococcic serum. The author notices Ball's statement in a recent lecture

that we should try to bring down the upper end of the anus more frequently than has been done. He does not favor the radical end-to-end union, but would invaginate the proximal end down into the interior of the distal end, at least one-half to one inch and strip off the mucous membrane of the upper part of the distal end to a corresponding extent. Where this is not possible, he thinks the sacral opening is the preferable procedure, but he does not stitch the open end of the bowel to the skin wound, but rather stitches the skin to the muscular coat of the bowel as far above the divided end as possible, and leaves the ligature on. If he can manage it, he stitches up the wound and completes the operation before cutting off the lower end of the rectum with the tumor. There is some objection to leaving the ligature on for awhile on account of the prevention of the escape of gas, but he has not found it necessary to do anything to relieve the patient before the ligature separates. He thinks in case of sacral anus benefit is derived from Gersuny's suggestion of giving the bowel a half or three-quarters turn before bringing it out. He follows this plan and finds it has great advantage in tending to continence of feces in the artificial opening.

5. **Carcinoma of the Stomach.**—Pollard finds that in some cases where the clinical symptoms point to obstruction of the pylorus from gastric carcinoma, operation is done with the idea of relieving the condition by gastroenterostomy and the growth is found away from the pylorus which is not obstructed. In these cases he believes gastroenterostomy is often still advisable, and reports a case where good results followed. His conclusion is that the clinical signs offer the most important indications for treatment. Where there seems to be obstruction, operation for its relief, even if the anatomic conditions do not indicate it, may be advisable.

7. **Blood Pressure.**—Oliver notices the fact of the rhythmic rise of blood pressure after eating, which is a little peculiar when we consider that the splanchnic arterioles dilate and should lower it. The arteriometer, however, shows that the arterial caliber is slightly lessened when the splanchnic diversion takes place, and there is a compensatory reduction of the systemic area of the circulation. He finds a certain amount of venous and capillary contraction which suggests that this increased blood pressure wave is associated with an exudation into the tissues of nourishing fluid during digestion. He also notices the effects of temperature on the blood pressure, and also of exercise, and finds that of all the three leading causes of arterial pressure variations, the influence of digestion is paramount and constant. The long curves of rise and fall produced by meals recur with regularity and persist beyond the temporary variations of blood pressure produced by muscular action and by temperature, which only modify the line of these curves in a mere transitory way. The article concludes with some observations on the influence of altitude on the blood pressure, which shows that it falls up to a certain altitude, say 2,000 or 3,500 feet, and above that is rapidly increased. He thinks these facts have a bearing on practical climatology. He is not aware of a climatic condition that will lower the mean arterial pressure to the same extent as the medium altitudes, and this might be considered in sending patients with plus arterial pressure to mountains in the winter months.

8. **Parasyphilis.**—The address by Ogilvie is an interesting one, criticising the theory of parasyphilitic disorders. He says all that is practically new in the modern teaching of parasyphilis, apart from the name, is the enormous extension given to the deleterious and deteriorating influence of syphilis on the race. The idea is not a new one. There is about one inch of discovery to a whole Pacific ocean of invention.

9. **The Curability of Epilepsy.**—Turner discusses the curability of epilepsy, giving an interesting tabulation of statistics and offers the following summary in conclusion:

"1. A total of 366 cases, chiefly derived from the out-patient records of the National Hospital for the Paralyzed and Epileptic, has been used for the investigation. 2. Only cases of genuine idiopathic epilepsy which had been under constant observation and treatment for a period of at least two years have been taken. All cases of symptomatic epilepsy, or cases otherwise complicated, were, as far as possible, eliminated. 3. The cases have been divided into three series, according as they have responded, successfully or otherwise, to treatment: arrested, improved and confirmed cases. The influence of the various conditions modifying prognosis has been mentioned in detail, the results of the observations being stated in the percentages. 4. A family history of epilepsy will be found more frequently among those who have become confirmed epileptics, but a hereditary history of epilepsy does not necessarily militate against the prospects of arrest or improvement of the disease in any given case. 5. The age at the onset of the disease has an especial bearing on the prognosis. The most unsatisfactory cases are those in which the disease commences under 10 years of age; they show the smallest percentage of recoveries and the largest of confirmed cases. If the disease arises between 15 and 20 years of age, an almost equal percentage of arrested and confirmed cases may be expected. The greatest percentage of confirmed cases is found among those in whom the disease begins between 25 and 35 years of age, from which time onwards there is a steady increase in the expectations of arrest and diminution in the number which become confirmed. 6. The duration of the malady influences the prognosis to the extent that arrest or improvement is much more likely during the first 5 than during the second 5 years. Cases, however, may be arrested even after a duration of from 20 to 30 years. 7. The greatest percentage of confirmed and the lowest percentage of arrested cases occur in those epileptics who are subject to daily or weekly attacks, while conversely, the smallest percentages of confirmed and the highest of arrested cases occur in those whose fits are as infrequent as once or twice a year. 8. The character of the seizures influences the prognosis to the extent that the major attacks are the most tractable; then follow combined major and minor seizures; and lastly, the minor attacks occurring alone. 9. Marriage exerts little if any influence on epileptic fits. Some patients are relieved and others are made worse. In the majority of cases the disease remains unaffected. 10. Pregnancy has little influence on the seizures; at the best there may be only a temporary respite. On the other hand, the puerperium would seem to be especially favorable for the recurrence of fits; while lactation also is not without an exciting influence in their production. 11. The common incidence of epileptic fits is an irregular periodicity. There are types, however, which have been described as "increasing" and "decreasing," according as the fits increase or decrease in number in a definite period of time, or in which there is a shortening or lengthening of the intervals between the fits. A case of increasing type may by treatment be converted into one of the decreasing variety. 12. Long remissions, induced either by successful treatment or from spontaneous cessation of the fits, sometimes lasting for several years, are not unusual in epilepsy; they are of favorable prognostic value, but are not synonymous with a cure of the disease. 13. From the collected statistics a period of remission for at least nine years has been fixed as the basis on which a cure of epilepsy may be established. With this definition of a cure I regard 10.2 per cent. of epileptics as curable. 14. There are some cases of epilepsy which may be regarded as belonging to a curable type of the disease. These present little or no mental impairment, notwithstanding that fits may have existed for a long period. In the cases in which arrest took place, cessa-

tion of the fits occurred within the first year of continuous treatment in over 50 per cent."

23. Sleeping Sickness.—Castellani finds in a large percentage of cases of sleeping sickness in the cerebrospinal fluid taken during life by lumbar puncture, a trypanosoma. It may be a new species, but rather closely resembles the *Trypanosoma gambiense* of Dutton. It is also found in the blood. He never finds it in the cerebrospinal fluid of other diseases than sleeping sickness. He has also cultivated from the blood of the heart and the liquid of the lateral ventricles in 80 per cent. of his postmortem cases a streptococcus which frequently shows cultural characters different from the *Streptococcus pyogenes*. He has rarely found this during life, and then as a rule *in extremis*. In the first stage of his investigation he attached much importance to the streptococcus, but at that time he had not found the trypanosoma. The facts, however, as regards the later discovery seem to him very suggestive and point to something more than a mere coincidence. He is inclined to conclude that sleeping sickness is probably due to the trypanosoma. At the same time there is frequently a concomitant streptococcic infection in the later stages which may play an important part.

40. Dermatoses as Cutaneous Reactions.—Brocq has been proclaiming for some time that lichen, pruritus, urticaria, eczema, psoriasis and erythemata are merely the way in which the skin of certain subjects reacts to certain influences. A single morbid cause may induce the most diverse eruptions in various subjects, and on the other hand, a single form of eruption may be induced by the most diverse causes. These assertions were confirmed by a recent experience at the Broca Hospital. Very strong coffee was served one day to 23 dermatologic patients, and the following day the 7 patients with dermatoses belonging to the above group all presented exacerbations of their cutaneous affection, while none of those with a dermatosis of another character showed any signs of aggravation of their condition. One of the patients had a severe case of eczema, and while under observation a marked aggravation of the condition was noticed on four occasions, once on account of fright in a storm, once on account of bad news, once the morning after a small epithelioma had been removed from her face, and again after ingestion of the coffee. Brocq has emphasized the relations between certain forms of pruritus, especially circumscribed neurodermitis, with daily ingestion of coffee.

44. Treatment of Muco-Membranous Colitis.—Langenhagen practices at the French watering-place, Plombières, and treats muco-membranous colitis by slow injection of one-half to two liters of water at a temperature of 100 to 118 F. The patient changes his position frequently to enable the fluid to rinse all parts of the intestine holding it, even assuming the knee-chest position. Langenhagen uses a canula of red rubber 30 to 40 cm. long, with two holes at the tip, and repeats the procedure twice a week to every day. It has proved successful in his experience in four-fifths of all cases, and only a very few displayed evidences of intolerance.

51. Dilution of Blood and Polyuria.—Loeper remarks in the course of this study of the balance between the blood and urine that there are certain cases of Bright's disease which require treatment along the lines of heart affections rather than on a purely osmotic basis. Cardiovascular diuretics are indicated, and puncture will relieve the local edema in a serous cavity. When it occurs in a lung, venesection allows the extravasation to return to its place in the circulating current. Cases of polyuria due exclusively to the defective functioning of the kidneys are comparatively rare. In a large number the kidney, obeying the impulse of the blood, plays the same regulating rôle, maintaining the balance and the volume of the blood as in normal conditions. This form of polyuria may have various origins, but the disturbance in the blood is the inevitable intermediary between the first cause and the polyuria, so that the blood stage always precedes the renal stage.

53. Artificial Abscesses in Intoxications.—Fochier's turpentine fixation abscesses are not taken very seriously in France, as a rule, but Arnozan and Carles report some astonishingly favorable results from their application in a number of cases of typhoid fever, pneumonia, meningitis and malaria, apparently otherwise doomed. They have also tried these abscesses in experimental intoxications and announce that in the pus they were able to discover two, three and even four times as much of the toxic substance introduced, copper, lead or arsenic, as in the same weight of tissue elsewhere in the animal. Applying these findings to man they obtained very satisfactory results in several cases of intoxication from carbolic or oxalic acid or carbonic oxid.

64. **Operative Treatment of Liver-Spleen Affections.**—The success of the Talma operation for establishing collateral circulation in case of cirrhosis of the liver is now established, on condition that it is undertaken before the lesions in the liver have become irreparable or the heart and kidneys are too much impaired. The best effects are attained in non-alcoholic cirrhosis, and especially in that of splenic origin. When the spleen is involved, Schiassi thinks it is important to associate with the omentopexy, a similar operation on the spleen, and describes three cases thus treated, the patients cured for a year or so to date. He shows that there are in reality two portal veins, the mesenteric vein and the splenic vein, one draining the intestinal region, the other the spleen. By diverting a part of the blood in the spleen through the wall, the excessive blood pressure in the organ is relieved and the toxins elaborated in the spleen are diverted elsewhere instead of being swept directly into the liver. Still another advantage of such an intervention is that as the circulation in the spleen becomes more active, it aids in restoring conditions to normal, and the biochemical processes are more rapid and less harmful. He illustrates with eleven large cuts the various steps of his method of combined omento- and spleno-pexy to produce a double complementary circulation. The two parts of the operation can be done at separate times. The ideal would be to place the spleen between the muscles and the peritoneum, but as the organ is frequently too much enlarged for this, he resorts to intra-abdominal fixation of the spleen, inserting a wick above and below to promote the formation of adhesions and for drainage. He works through an extensive right-angled incision, drawing the omentum out through the horizontal incision in the peritoneum and turning it down over the latter, spreading it out over as large a surface as possible. The fixation of the spleen is done through a vertical incision, a large curved needle carrying stout catgut is passed through the parenchyma of the organ and through the muscles and fascia of each lip of the vertical leg of the primary incision, with eight or nine interrupted stitches. This omento-splenopexy is particularly indicated for cases of primary splenomegalia with cirrhosis of the liver—the Banti syndrome, also for malarial splenomegaly with cirrhosis of the liver. Fixation of the spleen alone might be found useful in cases of splenomegaly in which the liver is apparently not involved to any extent, as in the splenic anemia of adults and in that of children, in the preascitic stage of Banti's disease, and in the Popoff-Gilbert type of splenomegalic cirrhosis.

67. **Uterine Intravascular Hemangio-Endothelioma.**—Hansen claims that the case he describes is the first on record. The patient was a woman of 52, otherwise healthy. The tumor weighed 6,900 gm., and there were no metastases. It had grown rapidly, causing anemia and emaciation. In structure it was partly sarcomatous and not definitely circumscribed.

68. **Osteochondrosarcoma of Thyroid.**—Funkenstein has found records of 3 cases resembling the 2 which he describes in detail. A sarcomatous spindle-celled neoformation containing cartilage and bone substance developed in the strumously degenerated thyroid gland in elderly subjects. The tumors also contained a fibrillary and hyaline intercellular substance. In one of his cases there was benign metastasis in a lung and a pure sarcoma in one suprarenal in the other case.

70. **Acute Lymphemia.**—The first symptoms were lachrymation and sticking together of the lids noticed in the year-old infant. Exophthalmus soon developed with pallor, diarrhea, vomiting and the physical signs of leukemia. The proportion of white to red corpuscles was 1 to 5; hemoglobin 21 per cent. The lymphocytes numbered 94.4 per cent., with 5.3 neutrophiles. Death soon ensued and macroscopic circumvascular infiltrates were found in the epicardium, periosteum of the ribs and in the pia mater. Microscopic infiltration was discovered also at the points usually affected.

72. **Calcification of Middle Coat of Arteries.**—Mönckeberg examined 130 subjects to determine the frequency of this alteration of the arteries of the extremities, and its relation to arteriosclerosis. Instead of its being a rare occurrence, he found pure media calcification in 55, with or without arteriosclerosis of the deep-seated arteries, and in 18 the sclerosis involved the peripheral arteries also. In 57 there was pure arteriosclerosis alone. Thus the media calcification occurs more frequently than arteriosclerosis, and is evidently often mistaken for the latter. Its degree and extent are no criteria for or against accompanying arteriosclerosis of the central vessels, as either may occur alone. The femoral artery is the one most frequently involved and chiefly affected by the calcifying process, and is sometimes the only one. In 12 of his subjects no other vascular affection could be discovered. The age of his total material ranged from 47 to 79, and it included workingmen, clerks, sailors, artisans, etc., both indoor and outdoor workers. There were no special alcoholic or venereal antecedents except in 2 and no chronic bone affection in any. Smallpox, cholera, dysentery and malaria were noted in the history of one case each, cancer in 4 and tuberculosis in the same number.

75. **Fat Transformation, Degeneration, Etc.**—Arnold classifies lipogenesis as exogenous and endogenous. The exogenous includes the physiologic migration of fat particles, fat embolism, fatty infiltration, and pathologic metamorphosis of fat, simple and necrobiotic, that is, the intracellular formation of fat according to the principles of synthesis and of phagocytosis. The endogenous (albuminogenous) includes the intercellular formation of fat from breaking down of albumin, and fatty degeneration.

82. **Intestinal Affections in Malaria.**—Glogner occupies an official medical position in the Dutch East Indies, and seven years' experience has convinced him that the dysentery, diarrhea and other symptoms of the so-called tropical dysentery are in many instances due to the action of the malaria parasite and vanish on exhibition of quinin. This is especially likely to be the case when diarrhea occurs intermittently, the periodicity suggesting that of malaria, without fever. In other cases there may be muco-bloody stools, violent pains, spontaneous and on pressure, with tenesmus and emaciation, and yet quinin soon banishes the syndrome. Negative examination of the blood does not exclude malaria unless in presence of fever. In these atypical, intestinal forms the malarial plasmodia are rarely discovered in the blood and yet the regular intermittency of the manifestations and the prompt response to quinin certainly indicate a malarial affection.

84. **Retrogression of Tophi.**—Rindfleisch examined under the microscope a tophus removed from his own olecranon process. He found that the deposit of uric acid was surrounded by a row of polynuclear giant cells, evidently phagocytes, which under favorable conditions devour the particles of the uric acid, and thus reduce the size of the deposit. He believes that this phagocytic action is scarcely possible, except in very vascular regions.

91. **Relations of Chloroma to Leukemia.**—A young glass-blower was admitted to the hospital with symptoms of transverse myelitis which proved fatal in a few weeks. The patient also presented the symptoms of acute lymphatic leukemia. The myelitis was caused by compression of the spinal cord by a large chloroma and similar tumors were found elsewhere in the periosteum and in close vicinity of the long bones, etc. Usually, the head and spine are exclusively affected, but sometimes the green lymphomata are located in the kidneys, lungs, mamma, testicles, broad ligaments, and as in the case described, in the urethra. The entire lymph apparatus and bone marrow exhibit hyperplasia, while the blood and mucosæ present the picture of acute lymphatic leukemia from which chloromatosis is only distinguished by the presence of the green tumors.

92. **Pathology of Diabetes.**—The case published by our American confrères was distinguished by the integrity of the pancreas while the gastrointestinal mucosa was in a condition of extreme atrophy with diffuse small-celled infiltration similar to what is observed in some cases of pernicious anemia.

94. **Epidemiology of Typhoid.**—In the recurrence of an epidemic of typhoid fever at Berne the proof was afforded that under certain conditions, as in standing water, typhoid bacilli may remain alive and retain their propagating and virulent qualities unchanged for several months.

95. **Principles of Immunization Against the Tsetse Fly Disease.**—Schilling thinks that the principles of successful immunization against the surra or tsetse fly disease are now thoroughly established. The property possessed by the parasite of adapting itself to its temporary host, may be utilized to attenuate its virulence for a certain species.

104. **Rapid and Effective Stain for the Gonococcus.**—Wahl thinks that he has solved the problem of producing a stain which keeps perfectly, stains the gonococci dark and the elements of the secretions another and lighter color, while the results are complete in five to fifteen seconds. He mixes 2 c.c. of a concentrated alcoholic solution of auramin with 1.5 c.c of 95 per cent. alcohol; 2 c.c. of a concentrated alcoholic solution of thionin; 3 c.c. of a concentrated aqueous solution of methyl green, and 6 c.c. of water. It is ready for use at once, and has kept unchanged for a year.

105. **Hemisystolia.**—As long ago as 1868 von Leyden described a case of what he called hemisystolia, non-synchronous contraction of the two ventricles. His assertions were disputed and he confesses that he has never seen but two cases since, and these not so marked as his first, which was reported in detail in *Virchow's Archiv* for that year, xliv, p. 365. The left ventricle contracted first without any perceptible participation of the right, and then the right without the participation of the left. It is a very rare phenomenon, and he is convinced that it never occurs except after large doses of digitalis. Openchowski has demonstrated on animals that the left heart beats nearly one-half slower than the right after injection of helleborin or digitalis, and is inclined to regard the right ventricle as immune to the action of these drugs. In a number of cases of mitral stenosis with dilatation of the right ventricle, von Leyden has noticed that digitalis had very little effect, and assumes that the thicker musculature is the reason why it acts more on the left ventricle than on the right. Broadbent, in his recent work, refers to the "supplementary systole of the right ventricle induced by digitalis." The phenomenon of hemisystolia is, therefore, being given more credence as time passes by physiologists and clinicians.

106. **Tuberculosis of Lymph Apparatus.**—The case reported was similar to that described by Sternberg in the *Ztft. f. Heilkunde*, 1898, xix, as a peculiar tuberculous affection of the lymphatic apparatus with the clinical picture of pseudo-leukemia. The patient was a man, a hair dresser, 28 years old, who had suffered from dysentery during military service in the tropics, also from malaria and recurring phlegmonous throat affections. The first symptoms were pains in the left arm and enlargement of the glands in neck and axilla, followed by night sweats and fever. The glandular affection and pains spread to involve other regions, the spleen and liver became hypertrophied with marked emaciation and general edema. The intensity of the pains required the continuous use of morphin, and the patient died in cachexia about fifteen months from the first symptoms. Pus was sometimes found in the sputa, but no tubercle bacilli. The blood count showed 10,000 leucocytes at first, but a polynuclear leucocytosis to 42,000 suddenly developed. Tubercle bacilli were found in the lymph glands and spleen and typical tubercles in the latter and in the liver. No evidence of what Sternberg styled "transitional processes of mercly inflamed parts into tuberculous tissue" was discovered.

108. **Prognosis of Cardiac Arrhythmia.**—Rehfisch refers to the fact that the functional activity of the heart is the product of its three inherent factors: its automatic excitability, the reaction to this excitability, that is, its power of conducting the stimulus, and lastly, its power of contraction. When any one of these factors is altered, arrhythmia in some form follows, and the prognosis depends on which of the factors is involved. In cases of abnormal excitability, shown in the extrasystole, which is the evidence of a disproportion between the power of the heart and the task required of it at the moment, the prognosis depends on the fundamental affection causing the extra excitability. This is usually arteriosclerosis, organic heart disease or pure nervousness. Knoll, by augmenting the resistance in the arteries, was able to elicit the extrasystole in his experimental research, similarly to what is observed in arteriosclerosis, either diffuse or of the coronary alone. The extra resistance imposes extra work on the heart, and this is followed by extra excitability. Nervous subjects come under this same law, as emotions are accompanied by variations in the blood pressure, which make extra demands on the heart and entail extra excitability and the extra systole. If arteriosclerosis and excessive nervousness can be excluded, then the extra systole is an evidence of organic heart affection, and hence its prognosis is grave, otherwise not. Of great importance in this case is the duration of the compensatory interval of rest, as he describes in detail with various pulse curves. The second factor in the cardiac function, the conductibility of the impulse, may be impaired by defective conductibility in the so-called block fibers, the muscular fibers connecting the atrium and the ventricle, which retain their embryonal type more than the others, and do not pass the impulse on so rapidly as the latter. They also are the ones to suffer first from any injury and if much degenerated, are able to arrest the impulse entirely, thus producing the "block heart." The distinguishing sign of disturbance in the conductibility is that the duration of one interval is always less than that of two pulse periods, and that the period following the interval is always longer than the second one. The irregular pulse of nervous and neurasthenic subjects is characterized by the grouping of the pulse beats. From 72 the pulse may jump to 96, but it never changes to a multiple of itself, a pulse of 48 does not follow one of 96, as in case of severe organic heart disease. In the missing pulse of nervous subjects the duration of the interval is much less than that of two pulse periods and seldom surpasses 60 per cent. of a pulse period. In case of acute infectious diseases the heart rallies all its energies and works with its utmost strength so that pulsus deficiens is not observed during the climax of the disease, but after the acute stage is past, then the heart relaxes its efforts, and we can then determine to what extent it has been impaired by the stress it has undergone, and the action of toxins, and what its loss in effective muscle substance and cell energy. If normal conditions are restored, the pulse will become normal also, but as long as the pulsus deficiens lasts it should be carefully supervised by the physician and the prognosis is not good. The prognosis of arrhythmia due to enfeebled contracting power is grave. Rehfisch states that he knows of only one case of pure pulsus alternans. This was published by Riegel, and he reproduces the curve.

111. **Autoserotherapy in Pleurisy.**—Gilbert's method of treating pleuritis by injecting some of the fluid derived by aspiration from the pleura was tried by Tschigaeff in 9 cases. In all the effusion ceased to increase after the injection and immediate absorption commenced. Acute serofibrinous pleuritis treated in this way was cured in about two weeks on an average. The earlier the injection was made, the prompter the recovery. No reaction to the injections occurred in cases of rheumatic origin, while in those due to tuberculosis there was always a brief febrile reaction. He describes a few typical cases in detail. One recovered after one injection, another required two, and a third four. The patients were from 18 to 66 years of age in these published cases. He aspirated about 5 c.c. of the serofibrinous effusion and reinjected subcutaneously 1 or 2 c.c. of it in the scapular region. No other treatment seems to have been instituted and the effusion was rapidly absorbed.

120. **Immunization Against Tuberculosis.**—Maragliano, in this address, delivered at the Madrid Congress, confirmed Behring's assertions in regard to the possibility of inducing passive immunization by means of the milk of immunized cows. He states that he has been experimenting in this line for five years, and has been able to isolate the protecting substance in the milk of the cows, although in small amounts, and has also established that antitoxin taken into the digestive tract is absorbed and displays its protective action on animals and man as when injected. Passive immunization can thus be realized by injection or ingestion of antitoxin. The antitoxic substances are found not only in the milk and blood but also in the meat of immunized animals. He proclaims that when a tuberculous focus anywhere on the body has completely healed, the individual is usually thereafter immune to tuberculosis. In families in which tuberculosis prevails, those members usually escape who have had a tuberculous joint or cutaneous affection or tuberculous focus elsewhere, from which they have completely recovered. When an individual has completely recovered from a local tuberculous affection, as a rule, he is therefore immune. Maragliano denounces the injection of living bacilli, no matter how attenuated, as dangerous, and contends that Behring is wrong when he asserts that active immunization is not possible save with living cultures. He has succeeded in inducing active immunity by injection of the tuberculous toxin alone, and has effectually induced the production of antitoxin and agglutination by this means. As early as 1891 he proclaimed that the action of Koch's old tuberculin was probably due to the elaboration of protecting substances in the body which it induced, and all his experimental and clinical research since has only confirmed this view. He has tried the tuberculin test again and again on some of his patients whom he has cured of tuberculosis with serum from immunized animals, and the results have always shown that the cure was complete during seven years' experience. None of his patients have changed their environment, one is a physician who continues his practice, constantly exposed to new infection. Maragliano is now engaged in the attempt to produce a tuberculous focus which will confer active immunity after healing, without the use of living cultures. He has been eminently successful on animals and has repeatedly induced an inflammatory tuberculous focus at the periphery with a mate-

rial which he does not describe more fully. Applying the results to man, he has been able to induce the production of agglutination and pronounced leucocytosis, the same as observed in animals, although in the clinic the crucial test of inoculation with tuberculosis is out of the question. He makes the artificial focus on the arm and a small inflammatory lesion develops, with sterile pus, and three days of fever, which then subsides and heals.

129. **Leucocytosis in Appendicitis.**—In examination of 40 patients with inflammation of the cecum Goetjes found that leucocytosis of 20,000 to 30,000 in appendicitis was the invariable index of a circumscribed suppurative process unless due to some complication. In case of diffuse peritonitis the blood count has no regular differentiating value except that high leucocytosis indicates a better prognosis.

132. **Abdominal Contusions.**—In distinguishing between a mere contusion and one accompanied by injury of some internal organ, Fraenkel emphasizes that the amount of shock is not always in proportion to the severity of the injury but that shock prolonged for more than six hours speaks for injury of some viscus. As the temperature is lowered in shock it is no criterion of the harm done at first, but a slight rise is an important indication of the escape of fecal masses or of accumulation of blood, bile or urine in the abdominal cavity, the temperature continuing to rise gradually. If the temperature taken hourly in the rectum is above normal and constantly rising, a severe internal injury can be assumed. The pulse is affected by the shock, but if it continues bad for hours and grows worse, an internal injury may be accepted. If vomiting occurs immediately it has no differentiating value, but if it first appears a few hours after the injury it indicates internal damage. But this tardy vomiting does not always accompany internal injury and to wait for it is to allow time for peritonitis to develop. Vomiting of blood indicates almost always gastric hemorrhage. The aspect of the abdominal walls is not conclusive, except the contraction. The abdomen may be drawn in like a crater. Meteorism is a symptom of commencing peritonitis. The abdomen contracts to rest the intestines, and this phenomenon is seldom absent in case of internal laceration of an internal organ. Pain is another important symptom, spontaneous or on pressure, localized or general throughout the abdomen. When it constantly increases in intensity it speaks for internal injury, but is not its inevitable accompaniment. The pain radiates to the shoulder in case of injury to liver and spleen. Percussion of the abdomen may reveal an exudate at once, but a small one in the lower pelvis is best discovered by palpation through the rectum, which should never be neglected. The disappearance of the liver dulness is also a valuable sign, as it indicates the escape of gases from the intestines or displacement of the liver by increasing meteorism. None of these signs are pathognomonic, and the examination should be repeated from hour to hour by the same person. The patient should be taken to a hospital or clinic on suspicion of severe abdominal injury, and everything prepared for an operation once the diagnosis is assured, although it may not be needed. In the meantime absolute repose and total abstinence. Opiates should not be given during this period of observation, nor stimulants nor saline infusion. They all mask the true diagnosis. Camphor may sometimes be required in severe shock. The exploratory laparotomy should be a short incision in the median line under infiltration anesthesia. It can be enlarged as necessary under "ether drop" narcosis, which Fraenkel prefers in these cases, with an incision from the ensiform process to the symphysis, sometimes supplemented with transverse incisions, to enable all the injured points to be discovered and rapidly treated. Time saved is so much vital energy saved. Unless it is possible to flush the cavity with 20 to 30 liters of saline infusion or sterile water he prefers to refrain and sponge it dry. Recovery depends mainly on the after-treatment in many cases. Saline infusion here asserts its rights. Petry has reported 55 per cent. recoveries in those operated on within twelve hours, and 33 per cent. of those operated on in a few days, his statistics comprising 42 cases. Fraenkel has seen 17 recover out of 31 operated on within three days. In 30 cases of laceration of the spleen, 16 recovered after operation. The total statistics show that 50 per cent. were cured, and a large number were very severe, otherwise doomed cases.

134. **Syphilitic Gummata of the Mamma.**—Heller started to remove a large supposed cancer of the mamma in a woman in the tertiary stage of syphilis, but after opening into the tumor found that it was a gumma, and refrained. He has collected nearly 50 similar cases of gumma in the mamma in the literature, but can not find one in which the tumor was retromammary as in his case. All were cured in a few weeks by exhibition of potassium iodid.

138. **Early Recurrence of Fibrinous Pneumonia.**—Ebstein refers to the relative frequency with which pneumonia recurs later in the same individual, as compared to typhoid. The cases of early recurrence of pneumonia are much rarer, but in his forty-three years' experience he has encountered one which he describes in detail. A young man convalescing from fibrinous pneumonia affecting the lower right lobe had seven days free from fever, after which the temperature rose again to its former height and there was evidently a new infection, a new pneumonia, affecting the same lobe and terminating in convalescence as before after four or five days. He reviews the literature in regard to what he calls "tardy recurrence," and states that 81 patients out of 438 cases of fibrinous pneumonia at Göttingen had pneumonia recur later from two to eleven times. Rush still heads the list, however, with his patient who had pneumonia twenty-eight times. Wagner ob-

served 2 cases of "early recurrence" in 110 cases, and 2 occurred at the Berlin Charité in 440 cases of pneumonia. Grisolle stated that one-twenty-eighth of all his cases had these early recurrences, which he called relapses. One patient had three, and Binz has reported a case with two. A few other cases have been published, including 2 reported by Osler. In Ebstein's experience with typhoid fever he has observed 13 cases of recurrence in 300 cases of ordinary typhoid, and 1 in 600 of the exanthematous form. He cites in conclusion as a curiosity Diemerbroeck's observation of a family of 4 children from 8 to 14 who all had an early recurrence of smallpox directly after convalescing from the primary attack.

143. **Recurring Oculomotor Paralysis.**—Schilling relates a case in which this paralysis appeared first at the eighth year and then recurred now and then during the seven and a half years to date, the intermissions growing shorter as time passed and the attacks less severe. Each was accompanied by pains in the forehead and temple on the same side as the paralysis, vomiting and great depression. There were no symptoms of migraine during the intervals and no history of migraine in the family. There was paresis during the intervals of the paralysis between the attacks. He suggests as an explanation a congenital weakness of the nerve involved, which is overcome by the accumulation of metabolic toxins. This assumption is sustained by the fact that the patient stutters, and also by the discovery of a field of medullated fibers in the fundus of the eye on the side affected.

144. **Treatment of Sucking in of Nostrils During Inspiration.**—Menzel has found paraffin prothesis a complete relief for this condition.

146. **Hyperemia as a Therapeutic Measure.**—This article is merely a detailed review of the large book on the subject recently published by A. Bier of Greifswald, dedicated to Esmarch. It is the work of a skilful surgeon, who brought the light of his experience to bear on physiologic and pathologic processes and was able to discover some entirely new standpoints for therapeutics and to supply the scientific basis for a number of empirically established facts. He regards superheated air as the best measure for inducing active hyperemia, and a moderately tight rubber band as the best for the passive. If the band is too tight the cold congestion that ensues is a very dangerous condition. There should be no pain in this form of therapeutic hyperemia. In tuberculosis he advocates interrupted passive hyperemia with long pauses. He has found the Junod boot effective, made of glass. He is inclined to attribute the efficacy of derivation to the hyperemization of the part which it induces, and believes that the application of ice has a similar effect. His results agree with the modern theory that absorption occurs through the blood capillaries and not, as formerly supposed, through the lymph. He devotes considerable space to a review of the facts in regard to the hypertrophy of the part induced by active hyperemia, and shows that it is not a delusion but a fact, and may prove useful in aiding regeneration of parts. The bones frequently grow both in length and thickness, the epithelium proliferates and the connective tissue increases under the influence of both active and passive hyperemia. The effect of passive congestion is usually magical in gonorrheal joint affections, as in arthropathies of various kinds. Induced hyperemia is also effectual in the treatment of neuralgias and for promoting absorption in elephantiasis, effusions in the joints and extravasations, etc. Bier's various works have been reviewed in THE JOURNAL as published from time to time. His extensive experience has suggested a number of technical points to seek or avoid, which he enumerates, and has shown that the simplest apparatus is as effective as the most complicated.

148. **Tuberculin in Early Diagnosis of Pulmonary Affections.**—Freymuth considers Koch's old tuberculin as the most reliable, but places the limit of non-febrile temperature a little higher than Koch, 37.1 to 37.2 C. He commences with 1 mg. If there is no trace of a reaction he then injects 5 mg., in case of a suggestion of a reaction, only 3 mg. If a third injection is necessary, the amount is 5 mg., or in rare cases 8 mg. The reaction curve shows a very steep ascent after a small single dose, or a slight ascent after the first small dose and a steep ascent after the second. The first curve is the expression of quite recent infection. The second one is more frequent. Still another curve is observed in case of recent but very mild infection. There is no reaction to the small and medium dose, but the third induces a steep rise. He reviews his experience with 170 patients thus tested. He mentions that the sputa, after injection of tuberculin, frequently contain tubercle bacilli not discoverable before. The tuberculin test was particularly useful in a group of 17 cases in which chlorosis masked the tuberculosis. The patients were young women or girls and the lung findings were trivial, with very little expectoration. They all reacted strikingly to tuberculin and yet the few clinical signs of tuberculosis, merely slight roughness in breathing and minimal decrease in the resonance, were so insignificant that the idea of tuberculosis scarcely suggested itself. Chlorosis alone does not react to tuberculin. Those cases are suspicious in which the general health is much impaired with comparatively slight diminution in hemoglobin, and those which iron fails to benefit. In all the cases of tuberculosis which reacted positively to the test the infection was recent or active. In more chronic benign, smouldering or healed infection the test was frequently negative. The same occurs with the imperfectly healed or stationary cases. His experience seems to demonstrate that the reaction is more powerful the shorter the interval since infection, before the organism has had time to elaborate any immunizing substance against it. In diagnosing, a negative result may signify no tuberculosis, but does not inevitably exclude it. Its chief importance is for the diagnosis of incipient tuberculosis when all other means have failed to disclose it.

160. **Hygiene in Syphilis.**—Block believes that the syphilitic toxin exerts its injurious influence on the vessel walls and nervous system from the very start, the effects resembling those of dissipation, over-exertion or chronic alcoholism. The nervous system is already predisposed by the stress of our strenuous life. In a less complex civilization the nervous system is not predisposed and offers more resistance, and is consequently not affected to the same extent. All the causes which tend to lower the resistance of the nervous system should be guarded against. The patient should be instructed to retire early. The food should be nourishing with milk in abundance. Alcohol predisposes to the severer forms of the disease and both alcohol and tobacco should be used in moderation or abandoned. Syphilitics like to read about the disease, and thus fall an easy prey to charlatans. To meet this craving Block has written a pamphlet, requesting them to refrain from reading other works on the subject. He insists on the patients returning at certain intervals for inspection, and reiteration of the warnings, etc., endeavoring to combat the depression, neurasthenia and mild hypochondria so liable to accompany the disease. A course of mineral waters may be useful, but under other circumstances he advises continuing at business. The patient should be instructed that a body once invaded by syphilis is thereafter less resistant, especially in the nervous and vascular systems, and although he can live a normal life, like other persons, yet he must keep within the bounds of a rational mode of life and abjure excesses of all kinds.

166. **The Hydro-Thermo-Regulator.**—Ullmann's coils of pipe or rubber tubing sewed flat on a sheet of asbestos or duck, with a continuous current of hot or cold water through them, have been described in these columns. This present article is elaborately illustrated.

171. **The Inventor of the Brand Bath.**—Sadger claims for a German physician, Dr. Pingler, the priority for the exclusive treatment of typhoid fever with cold water. He reported, in 1850, 26 cases thus treated, the mortality reduced to 7.6 per cent.

172. **Abortive Treatment of Furuncles with Dry Hot Air.**—Reich was impressed with the efficacy of this application in the abortion of 4 cases of incipient furuncles. None came to suppuration or necrosis. He thinks that if we restrict this "thermo-aerophor treatment," as he calls it, to true furuncles, and do not attempt to apply it in cases of deep-seated cellulitis or too late in the affection, we will never experience a failure.

175. **Physical Therapeutics for Affections of Testicles and Their Adnexa.**—Zabludowsky is in charge of the Berlin University Institute for Physico-Therapy and his report of the benefits derived from these measures has appeared in a number of our foreign exchanges, both French and German. The present article is copiously illustrated, and gives detailed directions for massage of the testicles, seminal cords, perineum and adjacent muscles, for cases of lingering inflammation of these parts of traumatic or gonorrheal origin, atrophy and functional disorders associated with nervous or psychic symptoms.

177. **Aronson's Streptococcus Serum.**—Meyer has used this serum in 18 cases, and states that the results were brilliantly successful in 3 cases of erysipelas, one of bilateral tonsillitis and one of severe puerperal infection. On the other hand, in several others the results were dubious, and in 2 others of erysipelas, 2 of scarlet fever, and 6 of septicemia, the results were entirely negative. The 5 successes encourage further trials and attempts to learn the reason for its failure in the other cases.

178. **Specific Treatment of Typhoid.**—Nammann has been able to collect 141 works on this subject. The general conclusions are favorable.

179. **The Rome Institute for Physical Therapeutics.**—Marcuse writes in longing envy of the beautiful and commodious model institute recently completed at Rome. The first floor is fitted up in classic style in imitation of the hot baths of the ancients, a most successful combination of the old Roman and Pompeiian baths, with modern comfort. The heating apparatus is beneath the floor, as in the ancient baths. The second floor is fitted up with the usual appliances of such an institution, with an amphitheater for teaching purposes, as the institution is affiliated with the university.

188. **Graphic Tracings of Kidney Functioning.**—Mircoli proclaims that very important information may be obtained from study of the specific gravity of the urine determined at different hours during the day. His research shows that the curve of the volume of water runs parallel to the curve of the specific gravity at different hours in normal subjects, but in case of kidney affections there is no parallelism and the kidney functions show various other aberrations. Among these is the absence of the normal diminuendo in kidney functioning observed during sleep. It seems as if in health the kidney slumbered also, while in case of a pathologic organ it may be functioning most intensely during sleep. The kidney, in comparison with the normal organ, behaves like a heart with tachycardia one-quarter and bradycardia three-quarters of every hour, or like a clock that gains time during the first quarter, but loses enough during the rest of the hour to nearly make it up or lose more. He has found the most convenient formula for this determination of renal functioning to be the specific gravity, computed for 1 c.c. of urine, multiplied by the number of centimeters of urine voided at all the natural urinations, this product divided by the number of hours. The result indicates the work actually done by the kidney and by determining it at various hours in the day a characteristic curve is obtained which will afford insight into the relations between renal functioning and the meals, exercise, sleep, etc., the number of urinations a day, the limits of the range of kidney functioning and the uniformity or irregularity of elimination of water and other substances. In health the curves from day to day always coincide at certain points, usually on rising, and at 10 a. m. After meals the kidneys work less at first and then resume their former activity. He suggests to accept 1 degree of specific gravity as the unit for renal functioning. The curve showing the amount of water parallels that of the specific gravity, except after ingestion of water or readily absorbed substances. After the critical elimination of this extra amount, the parallelism is resumed. It shows that the kidney in health always requires a given amount of water to eliminate a given amount of excrementitious substance, indicating harmony and co-ordination between the glomerular and canalicular apparatus. The lack of this parallelism in pathologic conditions is striking, and the way in which the curves cross and recross, capriciously to all appearance. In one instance he

noted this erratic curve after the kidney affection had been clinically completely cured. He urges others to study the curves of renal functioning and endeavor to determine their precise significance.

192½. Effects of Palpation of Kidney.—Morano concludes from his clinical experience corroborated by experimental research, that massage, or even palpation, has a directly injurious action on the kidney, especially if unusually accessible to the manipulations.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE PRACTICAL APPLICATION OF THE ROENTGEN RAYS IN THERAPEUTICS AND DIAGNOSIS. By William Allen Pusey, A.M., M.D., Professor of Dermatology in the University of Illinois; and Eugene W. Caldwell, B.S., Director of the Edward N. Gibbs X-Ray Memorial Laboratory of the University and Bellevue Hospital Medical College, New York. Cloth. Pp. 591. With 180 Illustrations, Nearly all Clinical. Price, $4.50 Net. Philadelphia: W. B. Saunders & Co. 1903.

PROGRESSIVE MEDICINE. Fifth Annual Series. Vol. II, June, 1903. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. Cloth. Pp. 427. With 46 Illustrations. Price, Per Volume, $2.50. Per Annum, in Four Cloth-Bound Volumes, $10.00. Philadelphia and New York: Lea Brothers & Co.

REPORT OF STREAMS EXAMINATION, Chemic and Bacteriologic, of the Waters Between Lake Michigan at Chicago and the Mississippi River at St. Louis, for the Purpose of Determining Their Condition and Quality Before and After the Opening of the Drainage Channel. Made Under the Direction of Arthur R. Reynolds, M.D., Commissioner of Health, City of Chicago. Pasteboard. Chicago: Blakely Printing Company. December, 1902.

PHYSIOLOGICAL ASPECTS OF THE LIQUOR PROBLEM. Investigations Made by and Under the Direction of W. O. Atwater, John S. Billings, H. P. Bowditch, R. H. Chittenden and W. H. Welch, Sub-Committee of the Committee of Fifty to Investigate the Liquor Problem. Vols. I and II. Cloth. Pp. 396 and 379 Respectively. Price, $4.50 Net Per Set. Boston and New York: Houghton, Mifflin & Co. 1903.

A TEXT-BOOK OF CHEMISTRY. For Students of Medicine, Pharmacy and Dentistry. By Edward Curtis Hill, M.S., M.D., Medical Analyst and Microscopist; Professor of Chemistry and Metallurgy in the Colorado College of Dental Surgery. With 78 Illustrations, Including 9 Full-page Halftone Colored Plates. Pp. xii-523. Cloth. Price, $3.00 Net. Philadelphia: F. A. Davis Company.

POSTMORTEM PATHOLOGY. A Manual of Postmortem Examinations and the Interpretations to Be Drawn Therefrom. A Practical Treatise for Students and Practitioners. By Henry W. Cattell, A.M., M.D., Pathologist to the Philadelphia Hospital. With 162 Illustrations. Cloth. Pp. 372. Price, $3.00. Philadelphia and London: J. B. Lippincott Co. 1903.

JAHRESBERICHT über die Fortschritte in der Lehre von den Pathogenen Mikro-organismen unfassend Bacterien, Pilze und Protozoen unter Mitwirkung von Fachgenossen bearbeitet und herausgegeben von Dr. med. P. von Baumgarten, und Dr. med. F. Tangl. Siebzehnter Jahrgang, 1901. Erste Abtheilung. Paper. Pp. 560. Leipzig: Verlag von S. Hirzel. 1903.

ANALYSIS OF THE SEXUAL IMPULSE—LOVE AND PAIN—THE SEXUAL IMPULSE IN WOMEN. Third Volume in Series, "Studies in the Psychology of Sex." By Havelock Ellis, L.S.A. (England); Fellow of the Medicolegal Society of New York and Anthropological Society of Berlin. Cloth. Pp. 266. Price, $2.00 Net. Philadelphia: F. A. Davis Company.

A TEXT-BOOK OF MODERN MATERIA MEDICA AND THERAPEUTICS. By A. A. Stevens, A.M., M.D., Lecturer on Physical Diagnosis in the University of Pennsylvania. Third Edition. Greatly Enlarged, Rewritten and Reset. Cloth. Pp. 663. Price, $3.50 Net. Philadelphia: W. B. Saunders & Co. 1903.

OCULAR THERAPEUTICS, According to the Most Recent Discoveries. By Dr. A. Darier. Translated by Sydney Stephenson, M.B., C.M., Honorary Secretary to the Ophthalmologic Society of the United States. Cloth. Pp. 278. Price, $3.00 Net. Philadelphia: P. Blakiston's Son & Co. 1903.

THE EXPECTANT MOTHER. A Treatise of the Care of the Expectant Mother During Pregnancy and Child-Birth and the Care of the Child from Birth to Puberty. By W. Lewis Howe, M.D. Cloth. Pp. viii-63. Price. $0.50 Net. Philadelphia: F. A. Davis Company.

SURGICAL ASEPSIS. Especially Adapted to Operations in the Home of the Patient. By Henry B. Palmer, M.D., Consulting Surgeon to the Central Maine General Hospital. 90 Illustrations. Cloth. Pp. vi-231. Price, $1.25 Net. Philadelphia: F. A. Davis Company.

THIRTY-NINTH ANNUAL REPORT OF THE TRUSTEES OF THE BOSTON CITY HOSPITAL. Including the Report of the Superintendent. For the Thirty-ninth Year, Feb. 1, 1902, to Jan. 31, 1903, Inclusive. Paper. Pp. 190. Boston: Municipal Printing Office. 1903.

INDEX-CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, UNITED STATES ARMY. Authors and Subjects. Second Series. Volume VII. Hernia Inquiry. Cloth. Pp. 1,003. Washington: Government Printing Office. 1902.

DISEASE OF THE PANCREAS. Its Cause and Nature. By Eugene L. Opie, M.D., Associate in Pathology in the Johns Hopkins University. Cloth. Pp. 359. Price, $3.00. Philadelphia and London: J. B. Lippincott Company. 1903.

TWENTY-SECOND ANNUAL REPORT OF THE STATE DEPARTMENT OF HEALTH OF NEW YORK. With Maps. For the Year Ending Dec. 31, 1901. Cloth. Pp. 632. Albany: J. B. Lyon Company. 1902.

THE BUCKEYE DOCTOR. A Tale for Physicians and for Physicians' Patients. By William W. Pennell, M.D. Cloth. Pp. 345. Price, $1.50. New York: The Grafton Press.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. A., under orders from the Adjutant-General's Office, Washington, D. C., for the two weeks ending June 13, 1903:

Appel, Daniel M., major surgeon, now at San Francisco, will proceed to Denver and report to the commanding general, Department of the Colorado, for further orders.

Chaffee, Jerome S., first lieut. and asst.-surgeon., is granted leave of absence, to include July 1, 1903, to take effect on his relief from duty at Fort Porter. The resignation of the above has been accepted, to take effect July 1, 1903.

Collins, G. L., first lieut. and asst.-surgeon, is granted leave for ten days from about June 14.

Daywalt, George W., contract surgeon, will, on the arrival at Fort Schuyler of Asst.-Surgeon Charles N. Barney, proceed to the artillery, District of Portland, and report to the district commander at Fort Preble for temporary duty at Fort Levett. When his services are no longer required in connection with the Army and Navy maneuvers he will, when relieved by the district commander, return to his station.

De Witt, Wallace, first lieut. and asst.-surgeon, now under treatment and observation at Fort McPherson, will proceed to Fort Porter for duty, to relieve First Lieut. Jerome S. Chaffee.

Duval, Douglas F., first lieut. and asst.-surgeon, is granted two months' leave of absence on surgeon's certificate.

Gregory, William G., contract surgeon, is relieved from further duty in the Division of the Philippines and, on the expiration of his present sick leave, will proceed to Fort Apache for duty.

Hart, James W., contract surgeon, will proceed from Fort Washington to the artillery, District of Portland, and report to the district commander for assignment to a station where his services may be needed. At the close of the maneuvers he will return to Fort Washington with the Thirty-seventh company.

Juenemann, George F., contract surgeon, now in Washington, D. C., will proceed to Fort Columbus for duty.

Pease, Louis W., contract surgeon, is granted an extension of one month's leave on surgeon's certificate.

Roberts, D. M., contract surgeon, is granted an extension of leave for two months.

Whitcomb, Clement C., first lieut. and asst.-surgeon, now at San Francisco, is relieved from further duty in the Division of the Philippines and will proceed to Governor's Island, N. Y., and report to the commanding general, Department of the East, for assignment to duty pertaining to the Army and Navy maneuvers during the ensuing year.

Stedman, Chester J., contract surgeon, now in Washington, D. C., will proceed to Fort Adams for duty.

Navy Changes.

Changes in the Medical Corps of the Navy for the two weeks ended June 20:

Surgeon L. W. Spratling, detached from the Navy Yard, New York, and ordered to the *Columbia*.

Surgeon P. Leach, detached from the *Columbia* and ordered to the *Massachusetts*.

A. A. Surgeon W. H. Block, detached from the Naval Recruiting Station, Chicago, and ordered to Navy Yard, New York.

Surgeon J. M. Steele, detached from the *Massachusetts* and granted leave for six months.

Surgeons Means, Cordeiro, Wieber, Norton, Kite, Wentworth, Decker, Berryhill, Stone, Pickrell, Crandall, Harris, Urie, McCormick, Arnold, Wilson, Stokes, Stitt, Gates, Lowndes, Barber, Rothganger, Smith, Lung, Von Wedekind, Bogert, Spratling, Kennedy, Blackwood, Braisted and Evans, commissioned surgeons, with rank of lieut.-commander, from March 3.

P. A. Surgeons Orvis, Kerr, Grow, Grunwell, Langhorne, Thompson, Benton, Garton, McCullough, Furiong, Angeney, Bell, Curl, Holcomb, Parker, Wright, Plummer, Odell and Taylor, commissioned passed asst.-surgeons, with rank of lieutenant, from March 3.

P. A. Surgeon D. H. Morgan, detached from the *Boston* and ordered to Naval Hospital, Mare Island, for treatment.

Drs. W. H. Rennie, W. W. Werner, O. Kohlhase and P. S. Rossiter, appointed asst.-surgeons from May 25.

Drs. W. B. Smith and W. S. Hoen, appointed asst.-surgeons from June 2.

Medical Director C. U. Gravatt, retired on account of disability incurred in active service.

Medical Director F. Anderson, detached from the *Alabama* and ordered to the *Brooklyn*.

Surgeon J. C. Byrnes, ordered to the *Texas*.

Surgeon C. J. Decker, ordered to the *Alabama*.

Surgeon C. F. Stokes, ordered to the Navy Yard, League Island, Pa.

Surgeon G. Pickrell, detached from the *Texas* and ordered to the *Iowa*.

P. A. Surgeon R. K. Smith, detached from the *Independence* and ordered to duty at the Naval and Marine Recruiting Stations, San Francisco.

P. A. Surgeon C. P. Kindelberger, detached from the *Iowa* and ordered home to await orders.

P. A. Surgeon A. Farenholt, detached from the *Boston* and ordered to the *Concord*.

Asst.-Surgeon M. K. Elmer, detached from the *Ranger* and ordered to the *Independence*.

Pharmacist W. H. Huntington, retired from active service on account of disability incident to service.

Medical Director J. B. Parker, retired from active service from June 20, under provisions of Section 1454, R. S.

Medical Inspector F. Anderson, commissioned medical inspector from January 31.

P. A. Surgeon J. S. Taylor, commissioned past asst.-surgeon from Nov. 8, 1902.

Drs. J. D. Manchester, P. T. Dessez and J. S. Woodward, appointed asst.-surgeons from June 10.

Medical Inspector S. H. Dickson, ordered home to wait orders.

P. A. Surgeon L. Morris, detached from the *Puritan* and ordered to the *Florida*.

A. A. Surgeon W. P. Keene, detached from the *Truxtun* and ordered to duty with the second torpedo flotilla.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the fourteen days ended June 18, 1903:

Surgeon D. A. Carmichael, leave of absence for seventeen days from May 19 granted by Bureau letter of May 9, amended so that it shall be for thirteen days only.

P. A. Surgeon J. M. Eager, granted leave of absence for two months from August 1.

P. A. Surgeon C. H. Gardner, granted leave of absence for seven days.

P. A. Surgeon H. B. Parker, directed to report at Washington, D. C., for temporary duty.

Asst.-Surgeon C. W. Vogel, granted leave of absence for one month from June 8.

Asst.-Surgeon B. J. Lloyd, to report to P. A. Surgeon R. Blue, Plague Laboratory, San Francisco, for temporary duty.

A. A. Surgeon J. E. Bready, granted leave of absence for three days.

A. A. Surgeon A. P. McConnell, granted leave of absence for two days from June 10.

A. A. Surgeon W. C. Mason, granted leave of absence for ten days from June 17.

A. A. Surgeon J. C. Rodman, granted leave of absence for thirty days from June 20.

A. A. Surgeon W. S. Walkiey, granted leave of absence for seven days from June 11.

Pharmacist G. C. Allen, granted extension of leave of absence for twenty-three days from June 5.

Assistant Surgeon-General A. H. Glennan, detailed as assistant surgeon-general in charge of the Domestic Quarantine Division in the Bureau of Public Health and Marine-Hospital Service.

Surgeon J. B. Stoner, granted leave of absence for one month from June 30.

P. A. Surgeon M. J. Rosenau, to proceed to Greenpoint, N. Y., for special temporary duty.

P. A. Surgeon J. A. Nydegger, relieved from duty at Cincinnati and directed to proceed to Sault Ste. Marie, Mich., as inspector of immigrants.

P. A. Surgeon E. K. Sprague, granted leave of absence for seven days from June 4, under Paragraph 191 of the regulations.

P. A. Surgeon S. B. Grubbs, Bureau telegram of May 13, 1903, granting P. A. Surgeon Grubbs leave of absence for one month, amended so that said leave shall be for one month from May 23.

Asst.-Surgeon C. E. Decker, granted extension of leave of absence, on account of sickness, for twenty-two days from June 9.

Asst.-Surgeon C. E. D. Lord, relieved from duty at Galveston, Texas, and directed to report to medical officer in command at San Francisco Quarantine for assignment to special duty.

A. A. Surgeon H. C. Sibree, granted leave of absence for six days from June 16.

Pharmacist C. G. Carlton, granted leave of absence for thirty days from June 1.

BOARDS CONVENED.

Board convened for the examination of Asst.-Surgeon M. K. Gwyn to determine his fitness for promotion to the grade of passed assistant-surgeon. Detail for the board: Assistant Surgeon-General L. L. Williams, chairman; Assistant Surgeon-General W. J. Pettus; Asst.-Surgeon V. G. Heiser, recorder.

Board convened for the examination of Asst.-Surgeon W. C. Hobdy to determine his fitness for promotion to the grade of passed assistant-surgeon. Detail for the board: Assistant Surgeon-General L. L. Williams, chairman; Assistant Surgeon-General W. J. Pettus; P. A. Surgeon L. E. Cofer, recorder.

Board convened at San Francisco, June 8, for the physical reexamination of an officer of the Revenue Cutter Service. Detail for the board: Asst.-Surgeon Carl Ramus, chairman; Asst.-Surgeon C. W. Vogel, recorder.

Board convened at Washington, D. C., June 10, to review testimony and make recommendation in case of Asst.-Surgeon F. J. Thornbury. Detail for the board: Assistant Surgeon-General W. J. Pettus, chairman; Surgeon H. W. Sawtelle; Surgeon D. A. Carmichael, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the two weeks ended June 20, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, May 30-June 3, 3 cases.

California: Fresno, May 1-31, 13 cases; Los Angeles, May 23-June 6, 5 cases; San Francisco, May 24-June 7, 5 cases.

Colorado: Denver, May 2-23, 70 cases.

Connecticut: Stamford, May 1-31, 1 case.

Florida: Baker County, June 6-13, 1 case; Columbia County, May 23-30, 1 case; Duval County, May 23-June 13, 7 cases; Escambia County, Pensacola, May 23-June 13, 3 cases; Leon County, May 23-30, 5 cases; Levy County, June 6-13, 10 cases.

Georgia: Atlanta, May 28-June 3, 2 cases.

Illinois: Belleville, June 6-13, 3 cases, 1 death; Chicago, May 31-June 6, 12 cases; Danville, May 31-June 6, 1 case.

Indiana: Evansville, June 6-13, 2 cases; Indianapolis, May 31-June 6, 2 cases.

Iowa: Des Moines, May 31-June 6, 1 case.

Louisiana: New Orleans, May 31-June 13, 5 cases.

Maine: Bucksport, June 3, 1 case.

Maryland: Baltimore, May 30-June 6, 1 case.

Massachusetts: Fall River, May 30-June 6, 9 cases; Holyoke, May 31-June 6, 2 cases.

Michigan: Detroit, May 28-June 13, 28 cases, 1 death; Flint, May 23-June 13, 3 cases; Grand Rapids, May 28-June 13, 7 cases; Port Huron, June 1-13, 2 cases.

Minnesota: Winona, May 30-June 13, 2 cases, 1 death.

Nebraska: Omaha, May 29-June 6, 3 cases.

New Hampshire: Nashua, May 29-June 13, 16 cases.

New York: New York, May 29-June 6, 1 case; Rochester, May 24-June 7, 3 deaths.

Ohio: Cincinnati, May 28-June 13, 7 cases, 1 death; Cleveland, May 30-June 6, 5 cases; Dayton, June 6-13, 6 cases; Hamilton, May 30-June 13, 2 cases; Toledo, May 16-30, 8 cases.

Pennsylvania: Altoona, May 29-June 6, 3 cases; Erie, May 29-June 6, 1 case; Johnstown, May 29-June 6, 1 case; McKeesport, May 29-June 13, 4 cases, 1 death; Philadelphia, May 29-June 6, 31 cases, 4 deaths; Pittsburg, May 29-June 6, 9 cases, 6 deaths.

Rhode Island: Warwick, June 8-15, 4 cases.

South Carolina: Charleston, May 28-June 13, 6 cases.

Tennessee: Memphis, May 23-June 6, 6 cases; Nashville, May 23-30, 1 case.

Texas: San Antonio, May 1-31, 2 cases.

Utah: Salt Lake City, May 31-June 6, 23 cases.

Wisconsin: Milwaukee, May 23-June 13, 70 cases.

SMALLPOX—INSULAR.

Hawaii: Honolulu, May 7, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, May 16-23, 4 cases.

Belgium: Antwerp, May 16-23, 6 cases; Brussels, May 16-23, 8 deaths.

Brazil: Rio de Janeiro, May 3-10, 5 deaths.

Canada: Amherst, N. S., June 12, 3 cases; Fredericton, N. B., June 12, 5 cases.

Canary Islands: Las Palmas, May 9-16, 18 cases.

China: Hongkong, April 11-25, 2 deaths; Shanghai, April 24-May 2, 3 deaths.

Colombia: Barranquilla, May 17-31, 1 case, 1 death; Bocas del Toro, May 19-June 2, epidemic.

France: Paris, May 8-30, 3 deaths.

Great Britain: Birmingham, May 23-30, 7 cases; Bradford, March 30-May 23, 100 cases, 5 deaths; Bristol, May 23-30, 1 case; Dublin, May 16-30, 26 cases, 4 deaths; Dundee, May 8-16 and 23-30, 10 cases; Leeds, May 23-30, 21 cases, 3 deaths; Liverpool, May 16-30, 82 cases, 10 deaths; London, May 16-30, 29 cases; Manchester, May 16-23, 14 cases; Newcastle-on-Tyne, May 8-16 and 23-30, 4 cases, 1 death; Nottingham, May 16-23, 2 cases; Sheffield, May 8-16 and 23-30, 5 cases; South Shields, May 8-16 and 23-30, 2 cases; Sunderland, May 23-30, 1 case; West Hartlepool, May 16-23, 2 cases.

India: Bombay, May 5-19, 111 deaths; Calcutta, April 11-18, May 2-16, 6 deaths.

Japan: Kobe, April 25-May 2, 6 cases.

Mexico: City of Mexico, May 17-31, 31 cases, 13 deaths.

Russia: Moscow, May 8-23, 8 cases, 2 deaths; Odessa, May 16-30, 4 cases, 1 death; St. Petersburg, April 25-May 30, 1174 cases, 24 deaths; Warsaw, April 18-May 16, 10 deaths.

Straits Settlement: Singapore, April 18-May 2, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, May 3-10, 8 cases.

Colombia: Panama, May 18-June 1, 10 cases, 6 deaths.

Costa Rica: Limon, May 21-June 4, 7 cases, 3 deaths.

Mexico: Coatzacoalcos, May 23-30, 1 case, 1 death; Progreso, June 3, 1 case; Tampico, May 23-June 8, 34 cases, 14 deaths; Vera Cruz, May 23-June 6, 42 cases, 12 deaths.

CHOLERA—INSULAR.

Philippines: Manila, April 11-May 2, 52 cases, 47 deaths; Provinces, April 11-May 2, 1,342 cases, 729 deaths; not previously reported, 81 cases, 79 deaths.

CHOLERA—FOREIGN.

China: Canton, May 8, 50 deaths; Hongkong, May 1-8, 2 cases.

India: Bombay, May 5-19, 1 death; Calcutta, April 11-18, May 2-16, 254 deaths.

Turkey: Dasmascus, March 29-April 16, to May 15, 94 cases, 117 deaths.

PLAGUE—UNITED STATES.

California: San Francisco, June 5, 1 death.

PLAGUE—FOREIGN.

Africa: East London, April 12-25, 2 cases; King Williams Town, April 12-25, 5 cases; Port Elizabeth, April 12-25, 15 cases.

China: Hongkong, April 11-25 and May 1-8, 225 cases, 202 deaths.

India: Bombay, April 11-18 and May 5-19, 740 deaths; Calcutta, April 11-18 and May 2-16, 758 deaths; Karachi, May 3-17, 332 cases, 292 deaths.

Japan: Yokohama, May 8-16, 2 deaths.

Peru: Callao, May 3-12, 10 cases, 6 deaths.

The Journal of the American Medical Association

Published under the Auspices of the Board of Trustees

VOL. XLI. CHICAGO, ILLINOIS, JULY 11, 1903. No. 2.

Address.

THE STATUS OF THE SECTION ON OPHTHALMOLOGY.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON OPHTHALMOLOGY, AT THE FIFTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT NEW ORLEANS, MAY 5-8, 1903.

JOHN E. WEEKS, M.D.
NEW YORK.

The By-laws of the American Medical Association provide that the chairman of each section shall present "an address on recent advances in the branches belonging to his Section, including such suggestions in regard to improvements or methods of work as he may deem important." This defines the character and limits the scope of his address and is, no doubt, a wise provision. Certain departures from the letter of the law are, I infer, permissible and, in pursuance of this belief, I shall digress sufficiently to welcome you all most heartily to this session of the Section, also to offer you my sincere thanks for the splendid manner in which you have supported the officers of the Section in their endeavor to present a program full to overflowing of valuable papers.

Some years ago Dr. Casey A. Wood, acting under Section 3 of the Constitution, which empowers officers of Sections to invite distinguished physicians of foreign countries to become members of the Association for the year and to participate in the affairs of the Section, endeavored to have a distinguished ophthalmologist of Paris attend the session of the Section. An invitation was extended and accepted, but at the last moment word was received that it was impossible for the gentleman to be with us. Last year our then chairman, Dr. Frank Allport, gave us the privilege and pleasure of meeting Professor Haab of Zurich, Switzerland, and of welcoming him to our country and to full participation in the affairs of our Section.

The precedent established by my able predecessors is one that, in my opinion, should be continued, not only because it serves to bring us in contact with men who are leaders in our branch of medicine, but because of the incentive to better work that such contact engenders. I have endeavored to emulate the example set me, with results similar to those of Dr. Wood.

The Section on Ophthalmology of the American Medical Association should be, as I believe it now is, the representative body of ophthalmologists in the United States. Its membership area is wider than that of any other society. As a part of a great Association of representative medical men, it has collateral support, and it is founded on a Constitution and governed by By-laws sufficiently broad and liberal to permit of indefinite expansion. The method of officering the Section provides against the danger of the domination of cliques and of the continuation of officers through courtesy or otherwise that might endanger its activity. The possibilities of the Section are great, and we should all endeavor to cause these possibilities to be realized by lending our influence to the production of work of the highest order and by making the meeting of the Section of the greatest possible interest.

The inducements to become identified with the Section are more than those afforded by any other association of ophthalmologists in this country. Some of them may be enumerated. First, contact with representative colleagues from all parts of the United States. Second, the assurance of large attendance. Third, the publication of accepted papers and the discussions of these papers in a journal having a larger circulation than any other medical journal in the United States, as well as the publication of papers and discussions in a bound volume of transactions at a nominal cost.

In regard to the volume of transactions, the chairman would suggest that an opportunity be afforded to every member of the Section, whether he be present or not, to obtain a copy. This could be satisfactorily arranged by the Executive Committee.

It is scarcely necessary that your chairman should mention to any extent the recent advances in ophthalmology. These will be presented in better form and more *in extenso* by the members of the Section in the session on which we are now entering. Some lines of research which promise much to careful workers may be mentioned: The effect of the *x*-rays and of the Finsen rays on neoplasms, detached retina, deep inflammatory processes and suppurative processes deserves more study. The study of the bacteriology of the eye is not yet exhausted; there are still some acute processes, apparently of bacterial origin, the causative agent of which is not known, among which may be mentioned Parinaud's conjunctivitis, trachoma and some of the suppurative diseases of the cornea. The question of the value of subconjunctival, intra-orbital and intrabulbar injections is yet in a chaotic state. This is a question which possesses potentials for much good to our patients. An exhaustive paper on orbital neoplasms, embracing the results of a careful study of all varieties by modern methods, would be heartily welcomed by all ophthalmologists.

Original Articles.

THE VALUE OF ENTEROSTOMY IN SELECTED CASES OF PERITONITIS.*

F. B. LUND, M.D.
BOSTON.

Among the many serious aspects in which that protean disease, appendicitis, is presented to the surgeon, there is none more alarming than the types in which diffuse peritonitis is attended with intestinal paralysis and distention of the abdomen. Here we have in addition to the already severe septicemia due to absorption from the peritoneum, a toxemia from absorption of the poisonous products of stagnating feces in the intestine, and the great depression produced by gaseous distention of the bowel. The mechanical interference with the descent of the diaphragm renders respiration feeble and shallow, interferes with the aëration of the blood, and adds the grave complication of asphyxia to tax the failing strength of a patient already almost exhausted. It is hard to conceive of a more certainly fatal form of assault on the organism.

We all, as surgeons, are familiar with the insidious and dangerous character of those cases of appendicitis which are so often sent to our hospitals with a diagnosis of "intestinal obstruction"—cases in which with a normal or slightly elevated temperature and local signs perhaps indefinite, the great distention of the abdomen, the bright eyes, blue lips, and dry tongue tell the story of a diffuse peritonitis with intestinal paralysis, and warn us of the gravity of the case with which we have to deal.

It is in cases of this sort that we find the greatest difficulties in the operation, and must look most sharply for complications in the after-care, and it is to the treatment of cases of this type that I would briefly invite your attention. So dangerous seems to me this type of the disease that I can truly say that I would rather meet a case of diffuse peritonitis involving the whole abdominal cavity without paralytic distention of the bowel, than a more localized and dry form of the disease in which this complication is present.

A brief consideration of the nature and causation of this distention which we call paralytic is necessary to our further argument. This distention is a complex phenomenon in which several causes may reasonably play a part. In its production may be concerned: First, obstruction of the bowel by angulation, due to fresh fibrinous adhesions, and the prevention of peristalsis by these same adhesions when they involve an extended area of the bowel. Adhesions of this type are found early in the dry type of diffuse peritonitis.

A second causative factor may be the laming of the smooth muscular fibers by the infiltration of the intestinal wall with inflammatory products. In the early stages of appendicitis it is well recognized that the infiltration of the intestine in the region of the ileocecal valve may temporarily paralyze a local section of the bowel, and result in vomiting and distention which passes off as the disease subsides or is operated on.

A third causative factor may be the paresis of the musculo-nervous peristaltic apparatus by the effect of toxins absorbed by the central nervous system. The paresis resulting from this last cause may, for the purposes of our argument, be disregarded, as it will occur only in the latest stages of septicemia, and after our patient is reduced to the deepest stages of exhaustion by the absorption of toxic products.

In the cases in which distention comes on early in an attack before the patient is profoundly septic or soon after an operation, it is undoubtedly due to one of the first two causes, namely, adhesions from fresh fibrinous exudate, or paralysis of the musculo-nervous apparatus of peristalsis by the presence of exudate in the intestinal wall. Of these two causes, the first is probably the more important.

When we consider the complexity in the shape and position of the intestine, and the importance of free mobility both to the production of peristalsis and the prevention of obstruction, it seems remarkable that paresis and obstruction are not universal accompaniments of peritonitis. It is obvious that a central peritonitis, such as arises when the appendix or other infecting organ is centrally situated, among the freely movable coils of small intestine will be more apt to cause intestinal paresis than a peripheral process situated, for instance, on the outer side of the fixed ascending colon, and between the latter and the abdominal wall.

The greater comparative fixation and the greater caliber of the large intestine render it less liable to kinking from fresh fibrinous adhesions than the small intestine.

Distention due to the first cause, angulation or compression by adhesions is more properly termed obstruction than paresis. Kinking many follow a local process, an adhesion at a single point, and result in distention of the entire intestine above that point. Multiple and extensive adhesions to other viscera and the abdominal wall may result in multiple angulations, and at the same time hamper the intestinal muscles, and these two processes may be associated in a greater or less degree with actual laming of the muscle itself by infiltration about and between the fibers. The exact part played by either process does not interest us, as the result is the same and the treatment indicated is the same, namely, to furnish a safe and easy exit to the contents of the over-distended bowel in order to allow it to collapse and recover its muscular tone.

In the milder cases it may be sufficient to stimulate peristalsis by irritating enemata of turpentine, glycerin and Epsom salts, and remove by the use of the rectal tube the obstruction from the contraction of the sphincter. These methods should be and are, of course, always tried before resorting to enterostomy. Enterostomy is a serious procedure; it subjects the patient certainly to the annoyance and discomfort of a fecal fistula, and generally to the danger of a secondary operation for the closure of the opening. The operation is, however, a simple one; it may be performed under local anesthesia, and the secondary operation is generally also simple and safe. It is proposed only in cases practically moribund from septicemia, asphyxia, from pressure upon the diaphragm, and often continually vomiting feces. The rescue of a few of these patients who, if let alone, are face to face with certain death, is certainly an adequate recompense for the slight inconvenience of the operation and the fecal fistula. In these cases, then, after other means have failed, the operation, it seems to the writer, is distinctly indicated, and in his experience and that of his colleagues it has been the means of saving valuable lives.

Local anesthesia avoids the special danger of a general anesthetic in these cases, namely, depression and inhalation of vomitus.

A word as to the time for the operation. Certain surgeons, among them Dr. Mixter of Boston, advocate in

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

cases of diffuse peritonitis with distention, the establishment of an outlet for gas and feces at the primary operation by the simple procedure of incising the cecum and tying in a glass tube. This tube may be removed in four or five days after distention has been relieved and adhesions formed about the wound, and it is said that the fecal fistula rarely remains for so long a time as to require an operation.

The writer, however, has felt that a fecal fistula should not be established except as a last resort. He has had such good results from the free incision of the intestine and suture of the wound after emptying the bowel, and perhaps injecting a saturated solution of Epsom salts at the time, that he has deemed it wiser to limit the primary interference to the above-mentioned procedure, associated, of course, with drainage of the abdomen and the usual procedures for the treatment of the peritonitis. Enterostomy should, in his opinion, be reserved for those cases in which, after the primary operation, enemata have failed to move the bowels, and the patient's life is endangered by distention. Thus the patient is not subjected to the annoyance of a fecal fistula till other means have been tried, and both patient and operator are satisfied of its necessity.

This reasoning does not apply, however, to cases in which the operation is done on patients living at a distance who can not be under the surgeon's immediate personal care. Under these circumstances the writer believes it wiser to open the bowel at the primary operation rather than run the risk of the patient's dying from paralytic distention before he can reach him for the secondary procedure.

In a case of general peritonitis with distention operated on this winter in the country, the writer did not open the bowel at the primary operation and returned to the city. The attending physician was kept away during the night following the operation by an obstetric case, and could not open the bowel, and the patient died of extreme paralytic distention early in the morning of the day following the operation.

Under such circumstances, immediate ileostomy or cecostomy would be distinctly advisable.

Instead of opening the cecum the writer has opened the small intestine, for the following reasons:

1. The fibrinous adhesions which cause the obstruction are probably located in the region of the ileocecal valve, and affect the small intestine above that valve. It is manifestly important to open the bowel above the point of obstruction, therefore a coil of small intestine which by distention shows that it is above the main point of obstruction is chosen.

2. The difficulty of the operation for resection and closure of a fecal fistula in the small intestine has, in the writer's hands, been considerably less than a similar operation on the cecum, because the small intestine can be brought outside the abdomen and operated on extraperitoneally, which is not always the case with the cecum. Lennander, who advocates opening the cecum at the primary operation or arranging gauze packing so as to have a surface of it exposed in the wound for subsequent incision, regards the opening of the small intestine as hazardous, owing to the uncertainty as to the distance of the point opened from the cecum. He has found in his experience that the coils of small intestine below the fistula become united by adhesions into a complex and undecipherable mass, and that if the patients lived, an ileocolostomy was necessary in order to cure the fecal fistula. The writer has not had this experience, although, as will be seen in the report of Case 3, an intestinal resection was necessary for chronic obstruction following enterostomy and closure of the fistula. This operation, however, was necessitated by adhesions above the ileocecal valve, so that it is difficult to see how opening the cecum would have relieved the obstruction in the first place, or how the fact that the ileum was opened had anything to do with their causation.

The advantages, then, of this method of ileostomy over cecostomy are that the intestine is certainly opened above the obstruction in case it is a kink in the cecal region, and the comparative simplicity of the operation for closure of the fistula. The bowel below the opening in the writer's cases never became so empty as to be adherent in a tangled mass, as shown by the fact that contents constantly passed through them, as shown by the abundant bowel movements. It is certainly a fair question whether the same result would not have happened had the cecum been opened instead of the ileum.

For the cecal operation the advantage is claimed that enemata, cathartic and nutritive, may be administered at once through the tube. The same treatment may be administered through a fistula into the small intestine. The primary point, it seems to the writer, is to get the intestine opened above the kinked or paralyzed portion, and enable the over-stretched muscles to get rid of their stagnating contents and recover their tone.

A word as to the technic: Local anesthesis with cocain solution (0.1 per cent.) should always be employed, owing to the danger of inhalation of fecal vomitus. The patient need not necessarily be removed from bed, but it is better to place an operating table in the room beside the bed, and gently lift the patient onto it. After cocainizing the skin and subcutaneous tissue, an incision one inch long is made in the median line below the umbilicus. The aponeurosis is then quickly infiltrated and the abdomen opened. The nearest distended coil of small intestine is sutured to the aponeurosis around the opening by a continuous suture of Pagenstecher thread, opened, and a large catheter of glass tube inserted a short distance into the afferent coil so as to prevent valve formation at the opening. An escape of a moderate amount of gas and perhaps feces takes place at once, and the patient generally expresses relief even for the slight diminution of distention which is at once evident. The operator need not be disappointed that the immediate amount of feces passed is small. A large gauze dressing is applied over the wound, which is kept separate from the other laparotomy dressing by a partition of rubber tissue stuck down to the abdominal wall with a strip of adhesive plaster.

In the course of a few hours, as the over-stretched intestinal muscles regain their tone, there follows a copious discharge from the opening, and generally the relief of tension allows the bowel below the opening to begin to act, so that enemata are successful in obtaining movements from the rectum. The pulse begins to fall within six to eight hours in successful cases.

The operation for closure of the fecal fistula may be done at any time after the patient has recovered his strength so as to be in good condition for it. The technic is simple, and, as employed by the writer and his colleagues, is as follows: The opening is first closed by coarse silk sutures passed through its border in the abdominal wall. Then the opening is circumscribed by an incision through the skin and muscle close to the border, the abdomen opened, and the adhesions freed around the

loop of the bowel. This is now drawn out of the abdomen and the margin of the opening with adherent skin, etc., excised till healthy bowel is reached. Then the opening in the bowel is sutured in a direction transverse to its axis (so as not to narrow the lumen) with through-and-through sutures of catgut. This line of suture is infolded by a continuous Cushing right-angled suture of Pagenstecher linen thread. The coil after being thoroughly cleansed with salt solution is then dropped back into the abdomen, and the wound in the abdominal wall closed with through-and-through sutures of silkworm gut around a small gauze drain passed down to the suture line.

In case the obstruction instead of being only temporary has remained permanent, owing to persistence of the adhesions, further operative procedures, even perhaps resection of the intestine, may be necessary for its relief, as in Case 3.

A comparison of the value of the writer's method with primary cecostomy is difficult owing to the rarity of reported cases. He awaits the reports of cases in which that procedure has been adopted in order to estimate its immediate efficacy and favorable after-results, which, according to the verbal report of surgeons connected with the Massachusetts General Hospital, have followed that procedure.

Statistical comparison with secondary cecostomy is also impossible on account of the rarity of reports of cases. In certain cases, cecostomy has resulted in saving the life of a desperately sick patient,[1] and in these cases there can be no doubt that the distention was paralytic, or the obstruction, if present, concerned the sigmoid.

Cases 1 and 3 of this paper, however, may be pointed out as cases which would probably not have been helped by this method.

The writer has the privilege, through the courtesy of Dr. John C. Munro and Dr. George H. Monks, in whose service they occurred, of reporting three cases of enterostomy for intestinal paralysis following operations for appendicitis, and is able also to report one case in which the same operation was done for peritonitis following a stab wound in the intestine. Dr. John T. Bottomley has also, April 24, just performed the operation in a case seen in consultation by Dr. Munro and the writer, in a patient dying from distention forty-eight hours after an operation for acute appendicitis. The patient was temporarily relieved, but died on the sixth day after the operation of septicemia. The report of the case is kindly furnished by Dr. Bottomley.

In addition to these cases reported in full, the writer has done the operation in one other case of peritonitis due to the perforation of the vaginal vault by a splinter of wood; in this case the relief of the distention was not sufficient to enable the patient to overcome the advanced septicemia from which she was suffering, and she died.

He has twice opened the presenting intestine adherent in the bottom of a wound of operation for general peritonitis following appendicitis without avail, the patients being already septicemic.

The operation has also been performed twice by colleagues at the writer's suggestion in cases of distention in advanced peritonitis, in both cases proving unavailing.

The writer does not advocate the procedure with any hope that it will prove uniformly successful, because many patients who may seem suitable for it will be found to be suffering from septicemia so severe that they can not recover strength after relief is afforded to the distended bowel. He does not advocate it either in all cases of general peritonitis which are progressing to a fatal termination after an unavailing laparotomy. But he does feel that there is a class of cases in which the obstruction or paralysis kills the patient rather than the septicemia, and that of these cases a certain number can be saved.

1. Madden: Lancet, London, 1902, 1533-34.

REPORTS OF CASES.

Case 1 may be summarized as follows: Operation on the fourth day of a subacute attack of appendicitis. Appendix adherent at tip to rectum in median line. Secondary enterostomy under ether for distention and intestinal paralysis 48 hours after the primary operation. Recovery. Operation for closure of fecal fistula after six weeks. Recovery. Good health two years after operation.

History.—C. P. B., 21 years old, single, a bank clerk, was admitted to the City Hospital as a private patient of Dr. J. C. Munro March 20, 1901. The patient had had a similar attack two weeks ago. Was seized the day before entrance with griping pains in the abdomen, which gradually grew worse. Vomited twice last night. Pain is not continuous, but at times is very severe. Feeling as if of pressing down on rectum. Abdomen distended, everywhere tympanitic. No tenderness or spasm. Temperature 98. Pulse 80.

Operation.—March 23. Ether. Median incision. Appendix three inches long, inside and behind cecum, base adherent to iliac vessels, coiled spirally on itself and with tip bound in adhesions deep in Douglas' pouch Ligated close to base with catgut. Stump cauterized with carbolic acid. Adhesions in pelvis broken up to free adherent loops, and cavity drained with iodoform gauze and glass tube. Appendix showed gangrenous inner coat, nearly perforated one-half inch from tip at site of old stricture.

March 25.—No movement of bowels since operation. Glass tube removed yesterday. Slight discharge. Wicks removed to-day. Cavity well walled off. Abdomen distended and tympanitic. Pulse 140. Ether. Incision in left iliac region. A small quantity of viscid fluid. No adhesions. Marked distention of bowels. A loop of gut brought to wound and roughly sutured to the transversalis fascia, and opened, but only a small amount of gas or fecal fluid escaped on account of the distention. Another loop adjacent was sutured and opened in same way, but evacuations of gas were unsatisfactory. Both loops were apparently small gut, but later it was shown that one was probably sigmoid. The original wound was explored and found clean and walled off. On breaking up adhesions and freeing a loop probably of small gut that was adherent deep in the pelvis and at a sharp angle, there was an immediate gurgle as of pent-up gas. The original wound was drained with iodoform gauze around a glass tube and separate dressings applied to each wound. Patient in very poor condition, almost constant regurgitation, poor rapid pulse, cyanosis, etc.

March 26.—Pulse 120. At 10 p. m. basin full of feces drawn by a catheter through artificial anus.

March 27.—Pulse still lower. Bowels kept flat by passing catheter into artificial anus. Feeding by mouth resumed, as nutrients came out through artificial anus. Progress good. Profuse discharge through artificial anus.

On April 25, four weeks later, the writer closed the artificial anus as follows: Incision was made into the abdomen just clear of the adherent loops which were dissected free from the abdominal wall and separated from each other. The granulating edges of the bowel were excised, the openings in each loop of bowel closed in a direction transverse to the lumen of the gut by three rows of Cushing continuous fine silk sutures, and returned to the abdominal cavity after thorough washing. No shock from operation. Good ether recovery.

The patient made an excellent recovery from this operation, leaving the hospital, May 18, and is now, two and one-half years later, in excellent health.

Case 2.—Summary: Operation for acute appendicitis 24 hours after beginning of attack. Secondary enterostomy for

intestinal paralysis 48 hours later under local anesthesia. Recovery. Closure of enterostomy four weeks later. Recovery. Good health one and one-half years later.

History.—W. B., 23 years old, salesman, was admitted to Dr. Munro's service at the Boston City Hospital on Nov. 21, 1901, 24 hours after the beginning of an attack of acute appendicitis. The abdomen was moderately distended and generally tender, the tenderness and rigidity being most marked in the region of the appendix. Temperature 100.2. Pulse 108.

Operation.—Dr. Munro operated on day of entrance by a muscle-splitting incision in the right iliac region. Abdomen full of serum and sero-purulent fluid, the purulent portion coming from the pelvis. A long, acutely inflamed appendix gangrenous in inner portion and hanging over brim of pelvis, was ligated with catgut and removed. As the general cavity was full of infected serum it was irrigated out with many quarts of salt solution and drained with a glass tube and iodoform gauze.

The following day he passed a little gas, but the pulse remained at 120 and the abdomen began to distend. The drainage wicks were started. The pulse fell to 90. The next day in the morning the bowels moved, but without relief of the distention, which increased during the day, and the patient was given several high enemata of turpentine without result. The pulse rose to 142 and was of poor quality. The patient was nauseated and weak.

The writer, in Dr. Munro's absence, saw him at 9 p. m., and in view of the increasing distention and rising pulse decided to perform enterostomy. Owing to the patient's poor condition and the danger of fecal vomiting under a general anesthetic, local anesthesia with 0.2 per cent. cocain solution was employed. An incision 1¼ inches long was made by the writer in the median line of the abdomen below the umbilicus, and the small intestine beneath was found injected and distended. A loop was sutured to the transversalis fascia by a continuous suture of Pagenstecher thread and opened, allowing escape of considerable gas and resulting in marked decrease of the distention. No shock attended the operation. Separate dressings were applied to the wound.

The following day the pulse fell to 112 and the distention was reduced by the passage of considerable gas through the artificial anus. Feces were soon passed by the rectum, but there was still abundant discharge from the wound until December 18, when Dr. Munro operated for closure of the fistula. The opening being closed by a temporary suture of silk, the incision was carried around the opening on each side through healthy tissue. There were no adhesions of the bowel except around the immediate edge, when it was sutured to the fascia. The loop of gut was brought out and the fistula excised. The opening was then closed by a row of Pagenstecher sutures, re-enforced by a Cushing right-angled continuous suture of pure silk. The wound was closed in layers with catgut and chromic gut.

Convalescence was normal, except for several attacks of vomiting and abdominal pain during the first week. The bowels moved freely and there was no distention. The patient left the hospital in good condition on Jan. 3, 1902. He is now, April 22, 1903, in excellent health .

CASE 3.—Summary. Operation for acute appendicitis with distention on fourth day of attack. Secondary enterostomy 48 hours later for intestinal paralysis and distention. Closure of enterostomy three weeks later. Five weeks later resection of intestine for partial obstruction. Recovery. In good health at time of report six months later.

History.—J. W., 11 years old, was admitted to the service of Dr. Monks at the Boston City Hospital on Oct. 28, 1902; four days before sudden pain in abdomen centering around umbilicus. Not radiating nor localized. Vomited frequently since onset of pain. No chills. Small movement resulting from enemata yesterday. General condition fair. Temperature normal. Pulse 100. Abdomen moderately and evenly distended. Coils visible. No peristalsis observed. Moderate general tenderness not at all localized. Moderate rigidity. Peritoneal facies.

Operation.—Ether. Median incision by the writer below umbilicus. Presenting intestine distended and injected. Free fluid, brownish and turbid. Incision enlarged to four inches, and intestine allowed to escape. Appendix found thickened, adherent, extending over pelvic brim into bottom of pelvis, where tip, covered with fibrin, lay in a small abscess cavity. Perforation ½ inch from end. Removal of appendix. At a point on the ileum near the ileocecal valve a large area of the surface of the bowel was covered with fibrin, evidently the seat of an adhesion. Below this point the bowel was not nearly so markedly distended as above. A coil of intestine above the adhesion was brought out over the side of the abdomen, opened and a large amount of feces allowed to escape. Saturated solution of Epsom salts was injected into the bowel and the opening sutured. Abdomen and pelvis flushed with salt solution. Bowel replaced and pelvis drained with glass tube and iodoform gauze wicks. Pulse 160 at close of operation.

October 29.—Occasional vomiting. Temperature normal. Pulse high and poor. Peritoneal facies, mildly delirious. No movement of the bowels or passage of gas.

October 30.—Abdomen considerably and evenly distended. Calomel, ¼ gr., every hour for eight hours without passage of gas. General condition worse.

Under cocain anesthesia an incision 1¼ inches long was made by the writer above the umbilicus. Presenting loop of small intestine, which was reddened and distended, sutured to transversalis fascia with silk. Small amount of gas and liquid feces escaped. Stimulated with strychnia, mildly delirious during operation. Not much relief from distention, probably due to atony.

October 31.—Good movement from turpentine enema. Now no distention.

November 4.—Profuse discharge from enterostomy wound and steady improvement.

November 7.—Attack of nausea and vomiting, with rise of pulse.

November 19.—One or two attacks of epigastric pain, nausea and vomiting.

November 21.—Ether and closure of enterostomy opening by the writer. Operation difficult on account of very extensive and firm adhesions to anterior abdominal wall. Separations of these adhesions difficult and attended by hemorrhage, which was controlled only by infolding the bleeding areas in silk. Opening in intestine carefully separated from abdominal wall and closed with Lembert sutures of pure silk. Further adhesions, very firm and fibrous, were noted to the lower part of incision, but it was not thought safe to separate them.

November 25.—Tendency to epigastric distention and occasional vomiting. Coils of intestine visible in epigastrium. Facies pinched. Occasional spasms of pain. Evidently partial obstruction. Operation discussed.

December 3.—Vomiting continual since last note. Distention continuing in spite of high turpentine enemata. Patient very restless. Facies pinched. Spasms of pain. Occasional passage of gas.

December 4.—Abdomen distended above umbilicus; coils visible.

Further Operation.—Dr. G. H. Monks. Ether. Incision in line of original incision below umbilicus. Abdomen opened freely. Great number of adhesions between intestines and peritoneum and between coils of intestine separated with difficulty, leaving large denuded areas of bowel which oozed freely and which could not be covered with peritoneum. At a number of places the adhesions had contracted the bowel, but not enough to reduce the lumen so as to endanger the fecal current. On following the jejunum toward the iliac fossa a marked contraction, cicatricial in character, was found, complicated by adherent omentum and bowel. The intestine beyond was collapsed; proximal intestine moderately distended. Adhesions were separated. The constricted portion of bowel was excised by removing a wedge-shaped segment 2 inches long on free border and one-half inch long on mesenteric border. Suture with continuous right-angled Cushing suture of fine silk. Patient's condition had become precarious, so that no effort could be made to stop oozing from denuded peritoneal

surfaces or to correct other partial constrictions which were found. The abdominal cavity was irrigated with salt solution and the wound hastily closed with interrupted silkworm gut. Small iodoform wick to seat of anastomosis. Rallied slowly from ether and operation.

December 5.—Slight delirium. Still distention. Pulse 140.

December 9.—Pulse 100. Vomiting ceased three days ago. General condition much improved. Distention disappeared. Abdomen soft. Good results from enemata.

December 14.—Rapidly improving. Soft solids by mouth.

December 28.—Gradually gaining. Diarrhea for past three or four days.

January 4.—Improving rapidly, though still much emaciated and pale. Diarrhea still. No distention.

January 9.—Still four or five liquid movements a day. Slowly gaining strength. Up and walking by aid of chair. He left the hospital on this date and reported on April 15, 1903, in excellent condition, having fully recovered his health and strength.

Case 4.—Stab wound of small intestine. Suture of wound and return of intestine followed by properitoneal hernia. Operation for hernia followed by peritonitis with distention and adhesion of a coil of intestine to operation wound. Enterostomy on an apparently dying patient followed by rapid recovery. Closure of fecal fistula six weeks later.

History.—D. M., 62 years of age, was admitted to the Quincy Hospital Feb. 2, 1903, to the service of Dr. N. S. Hunting, through whose courtesy the writer is permitted to report this case. While at a dance at 1:30 a. m. the patient was stabbed in the abdomen. He walked to the office of a physician, who probed and sewed it with catgut. Pain followed and he was admitted to the hospital at 3:30 a. m.

Operation.—He presented a crescentic wound ⅝ in. long one-half inch above and to outside of right spine of pubes. Three stitches were removed. Abdominal wall thin and bowel presenting. Drs. Hunting and Ellsworth operated. Wound enlarged and opened parallel to rectus. It was found that the muscles had been cut upward and outward parallel to and just above inguinal canal. Some free bleeding from cut edge. Punctured wound of ileum ⅛ in. long, from which yellow serum-like fluid exuded on pressure. Closed with two rows of silk suture. Inguinal canal closed with kangaroo tendon after washing out with salt solution. The patient did well for three days, then, on February 11, there was abdominal pain and obstruction which high enemata failed to relieve. Temperature normal. Pulse 60.

Second Operation.—Ether. Dr. Hunting operated. Wound enlarged and opened parallel to rectus. Bowel at site of injury in good condition. Wound tight. On further examination it was found that the peritoneum was deflected from level of anterior superior spine and 19 inches of bowel lay outside the peritoneum, i. e., a peritoneal hernia. Opening in peritoneum was constricting the gut. It would admit tip of finger. Peritoneum opened freely and bowel inside was found injected with flakes of fibrin. The bowel was replaced and cavity washed with salt solution. Peritoneum and wound sutured around a drain of iodoform gauze.

During next three days cathartics and enemata failed to induce movement of bowels.

February 17.—Abdomen distended, skin red, pulled apart.

February 18.—Pain and tenderness in right abdomen.

February 19.—Distention. Wound looks sluggish. Slough and purulent expectoration.

February 21.—Condition same. Distention very marked in spite of repeated small movements from $MgSO_4$. Regurgitates dark green fluid.

February 22.—Uncomfortable. Pulse and temperature good.

February 23 the distention became extreme. The patient was continually vomiting fecal matter and the pulse rose to 140 and became very weak. The writer was called in consultation and found the patient in very poor condition. It was decided to perform enterostomy. With local anesthesia an incision one inch long was made in the median line below the umbilicus. On opening the abdomen it was found full of pus. It was thought desirable to supply drainage for this pus before opening the intestine, and the writer therefore decided to reopen the original wound and insert a glass drainage tube through its lower angle into the pelvis before performing the enterostomy. On dissecting into this wound the intestine was accidentally opened and at once there took place a very free passage of gas and feces, and the patient expressed himself as relieved. The intestine was therefore sutured to the abdominal wall at the place where it had been opened and the other wound was abandoned. A third incision was made in the median line just above the pubes into the abdomen, and through this a drainage tube was passed into the pelvis and the pus washed out of the peritoneal cavity with salt solution. All these procedures were performed without difficulty under local anesthesia. After the operation the patient's pulse and temperature steadily fell. For the first few days feces were discharged through the artificial anus. Later he began to have movements of the bowels. The irritation of the skin of the abdominal wall by the escaping intestinal fluids was a source of considerable annoyance. The patient improved, however, and on April 18 the writer performed the operation for closure of the fecal fistula as described in the three preceding cases. At the time of writing, April 22, the patient was having a most satisfactory convalescence.

Case 5.—*History.*—R. R., 25, single, was recently operated on by Dr. John T. Bottomley, at the Boston City Hospital, on the third day of appendicitis. He found the appendix acutely inflamed, adherent to pelvic brim, free pus in the abdomen and fibrin flakes on the neighboring intestines. There were two perforations near the tip of the appendix. After excision of the appendix the wound was packed and drained freely with iodoform gauze. The abdomen was washed with salt solution. Cultures from the pus showed *Staphylococcus albus and Bacillus coli communis.*

The patient made a good recovery from ether, but for two days after the operation no gas or feces passed the bowels. The pulse gradually rose, and on the morning of the third day the patient began to vomit and vomited dark brown material frequently. The abdomen was distended. The pulse was 140 and he was very weak, cyanotic and evidently desperately ill. He was seen by the writer and Dr. Munro in consultation. Dr. Bottomley performed enterostomy under local cocain anesthesia, making a median incision through the abdominal wall below the umbilicus. On opening the abdomen the intestine was injected, but there was no excess of fluid in the cavity. A loop of intestine which presented under the wound was sutured to the aponeurosis of the rectus muscles by continuous silk sutures and opened. There was an immediate discharge of gas and feces. A bent glass tube was tied in to the intestine attached to a rubber tube which went over the side of the bed. Soon after the operation the patient stopped vomiting and was able to take liquids by the mouth. During the next three days his condition gradually improved. There was copious discharge of feces through the enterostomy wound. The bowels moved by the rectum under the influence of enemata. On the fourth day, however, the abdomen began to distend in spite of the movements of the bowels, and the pulse to rise. On the fifth day the patient began to vomit, and died on the morning of the sixth day.

In this case, it is evident that the operation did not save life, but its effect in relieving the patient was marked. He was moribund at the time when the operation was done, and the improvement which took place seemed almost miraculous. Hopes were entertained of his recovery. There is no question that he died of continued peritoneal infection, which in itself is sufficient to kill many patients even without obstruction of the bowels. No one regretted having made the attempt to save him by enterostomy, for it was felt by all concerned that everything had been done to save the man's life. At a partial autopsy it was found that the opening in the intestine was just 8 inches above the ileocecal valve.

SUMMARY.

Enterostomy is indicated for obstruction or paralytic distention of the intestine from whatever cause, after the ordinary means for relief of such distention have

failed. It is especially applicable for distention after operations for acute appendicitis or general peritonitis. Under such circumstances it may restore to life cases in which death seems inevitable. Secondary ileostomy is the operation of choice. Local anesthesia is to be preferred. The subsequent operation for closure of the fecal fistula is usually safe and successful.

DISCUSSION.

DR. M. B. TINKER, Baltimore—Enterostomy has been used in selected cases of this kind at the Johns Hopkins Hospital for the past five or six years. It was introduced there by Dr. Finney, but has been used only in a few cases, for the reasons given by Dr. Lund. It is very repulsive to the patient to have a fecal fistula; the skin is usually excoriated around the fistula, frequently causing severe pain, and it is very difficult to keep the patient clean. In the last three years I have not seen secondary operation necessary for the closure of fecal fistula, however. The intestine should be brought up to the abdominal wall and sutured; a tangential enterostomy which does not bring the gut outside of the abdominal cavity, as in colostomy. Some operators have made a mistake in bringing the gut outside of the abdomen, thus making a secondary operation always necessary. When the fistula persists, as it frequently does, for weeks, excoriation of the skin is a source of great discomfort, and the patients can be greatly relieved by putting them in a tub of warm water. Cases in which enterostomy is of great value are the cases of obstruction following perforation with localized peritonitis. To break up the adhesions and relieve the obstruction would mean the soiling of the entire peritoneal cavity. By the enterostomy we relieve the obstruction at once, and in most cases the obstruction coming from distention gives no further trouble after this is relieved. Leaving an enterostomy opening, instead of closing perforations in the intestines also saves lives in many cases. Dr. Follis did this in a case of typhoid perforation in which the patient was in an extremely low condition, and the very least intervention seemed indicated. This can be done much more quickly than suture of the perforation, and in the case mentioned the patient made an excellent recovery, in spite of his bad condition at the time of operation. In a case of gunshot wound of the abdomen with eleven intestinal perforations, the patient was brought into the hospital in a very low condition with the abdomen full of blood. Extensive intervention meant death, and instead of attempting to suture all the openings, a loop of intestine with four perforations in it was resected, the ends brought out to form enterostomy openings, and was gauze-packed about. Recovery followed in this case also. While not to be advocated in all cases, the use of this procedure in certain critical cases of obstruction from peritonitis has, I believe, saved a number who would have died from a more extensive operation.

DR. MILES F. PORTER, Fort Wayne, Ind.—Some years ago I had the honor of reading a paper before the Mississippi Valley Medical Association, in Detroit, in which this subject was referred to, and a year or two afterward, 1897, I read another paper on the subject of tympany. I tried to show in those papers that there were many cases of peritonitis that died that might and would have recovered had that one symptom been overcome. This statement I had at that time been convinced was correct by at least one case, and since then I have seen it corroborated in a number of cases. I have seen cases of peritonitis with enormous quantities of pus, in which the patient was in such a deplorable condition from the tympany that I felt warranted in relieving the tympany by opening the gut before I drained the abscess, and I have had the satisfaction of seeing at least one of these cases get well.[1]

The point that I wish particularly to emphasize is that many of these patients die because of the tympany, and if that is relieved the patient will get well, or so far recover as to enable one to perform an operation later to remove the original cause of the peritonitis.

Now, in regard to the occurrence of fecal fistula, I wish to emphasize a point made by the last speaker. The fistula will not need to be closed by the surgeon, if it is properly made to start with. If the gut is simply attached to the peritoneum, it will close itself and render a subsequent operation unnecessary.

DR. C. P. THOMAS, Spokane, Wash.—It appears to me that we—particularly the last speaker—are getting the cart before the horse. If we simply attach the bowel to the abdominal wall and make an incision in it, disregarding the pathology, we will get left in a great many cases. I do not believe one case in a hundred of fulminating appendicitis, for instance, where we always have intestinal paralysis, would get well if we simply did an enterostomy.

If we will first remove the cause of the intestinal paralysis, it will not often be necessary to attach the bowel to the abdominal wall and open it. After most intraperitoneal operations there follows some peritonitis, with obstructive symptoms; the time at which we can safely say a given case will recover, or not, without enterostomy, is not to me a definite one, and I believe the cases that recover with enterostomy would have done so without it. The half dozen cases that I have operated on, died, while others apparently as bad recovered without operation. I heard Professor Nicholas Senn once say that his experience had been the same.

We should not expect intestinal drainage to cure peritonitis, but should first remove the cause, leaving enterostomy as a last resort. High rectal injections of alum solution will often hasten normal bowel movement.

DR. JAMES B. BULLITT, Louisville, Ky.—I think we have gotten the cart before the horse, or at least the last speaker has, as I think there was no question raised by the essayists regarding the cure of appendicitis by making an enterostomy. The conception of the author evidently was that the cases of appendicitis should be dealt with in the best possible manner, and when, after the operations have been performed, the condition of the patient demands it, that this operation be done. I believe that all of us, who have not grown very old, perhaps, have been confronted by the most depressing problems. The patient that apparently should be getting well develops a tympany, and the surgeon is always undecided whether or not this tympany will be overcome in the particular case, or whether, if the tympany be unrelieved, the patient will be carried beyond the reach of the surgeon, and death result. Under these circumstances, I say that the younger members of the profession find themselves in the greatest embarrassment, and the older members of the profession, perhaps, are not prone to give them the greatest amount of comfort. Under these circumstances the operation as outlined by the author would seem to me to be the most rational form of procedure. It is one with which good surgeons have been familiar for many years. I am sure that in many cases it is the best and most conservative operation to do, as we can never tell just when these patients have passed the danger line, and if we do not do it, we have to trust to luck that the patient will pass safely by the probabilities of death on the next day.

DR. F. A. DUNSMOOR, Minneapolis—I thought when the essayist was reading his paper that I would have given much at his age to know what he does now, because I am sure we hear of many cases being relieved by this measure. I am sure the essayist doesn't mean to convey to any of the pessimistic men who wish to criticise him, that the operation will cure every person who has intestinal paralysis, obstruction, or who has infection, whether following an operation or a primary condition. It certainly is an important thing to recognize that there is an opportunity of preventing death following postoperative obstruction in this region. When we have made out the fact that our patient has been badly poisoned, either because of the pus previously present, or from operative infection, either obstructive or septic, then we know that something else has taken place within the intestinal tract beside digestion, and we also know that there is a large amount of toxic material there which is going to do harm. It can not get out if there is obstruction or paralysis of the bowel, and we should do as much as possible for relief with as little manipulation as possible, and not hunt all around the abdomen for the perforation. I believe patients have been killed

1. Medical News, July 31, 1897.

by attempts of surgeons to relieve the condition by suturing the perforation, the local poison being distributed to the general peritoneal cavity with overwhelming results. I open the gut, empty and wash it out, if possible, by means of the normal saline solution. I have not had the opportunity of trying the alum solution, but I am sure that I have seen cases cured, not only by the alum method, but by making a temporary window in the gut at the time, and doing a subsequent operation for relief of conditions present.

Dr. Fred B. Lund, Boston—In regard to the fistulas, I would rather close them than wait for Nature, and I think the patients would rather have this done. I do not advocate enterostomy in all cases of peritonitis, nor do I claim it is an unfailing cure. I expressly stated the fact that all other intestinal measures should be employed first, before this operation is undertaken.

PROLONGED INTUBATION TUBES,

WITH A METHOD LEADING TO THEIR EXTRACTION.*

BURT RUSSELL SHURLY, B.S., M.D.

Attending Physician, Woman's Hospital and Infants' Home; Junior Attending Physician, Harper Hospital; Lecturer on Physiology, Detroit College of Medicine.

DETROIT.

The field of modern scientific research can demonstrate few more valuable therapeutic triumphs than the results displayed by antitoxin and intubation in laryngeal diphtheria. The fondest hopes of Roux, Berhing and O'Dwyer have been realized. It remains for us, their pupils, only to defend and apply the principles which they have so perfectly laid before us. It would seem that results as marvelous as our collective investigations absolutely demonstrate ought to be sufficient, but there is much missionary work yet to be done. It is not uncommon to find at the present time many cases of laryngeal diphtheria under observation for some days without the administration of antidiphtheritic serum while operative interference is postponed until the patient is moribund.

During a recent trip abroad it was my privilege to meet those enthusiastic pioneers in intubation, Baginsky of Berlin, Egide of Rome, and Massei of Naples, and to find that their troubles with the retained tubes were the same as ours. In view of the brilliant results with intubation and antitoxin in America and on the continent, the incomprehensible antagonism of the followers of Lennox-Brown in England calls forth a most hearty condemnation. The reserve with which intubation is received in Great Britian is almost beyond pardon. A review of the literature of this operation in the *British Medical Journal* for the last decade reveals just seven references to it, six of which are short abstracts from articles published on the continent only, the other one embracing reports of the papers of O'Dwyer and Northrup which were read before the children's section of the British Medical Society.

The masterly thesis of O'Dwyer on retained tubes, and I believe the last important article which he published, is a contribution to our literature that can not be equaled. My work has been along the line of Dr. O'Dwyer's suggestions, and it is with the hope that a report of the results achieved with astringent applications to the larynx in such cases may lead to a wider field of usefulness for these agents that I present this subject for your consideration.

Prolonged intubation, as you know, is a term applied to conditions necessitating the use of an intubation tube for a longer period than six days, while "retained tubes" is an expression usually meant to include the prolonged period with a more extensive or indefinite course of time. Conditions rendering the continued use of the tube necessary are fortunately rare. Some observers report 2 to 3 per cent. of these cases occurring in each 100 operations. Extensive contributions to the literature have been made by O'Dwyer, Bokay, Chetalain, Rauchfuss, Trumpp and E. Rosenthal.

The observations and deductions which I have to make in this paper are gathered from a personal experience of 300 intubations, in addition to the use of antitoxin; 230 of these were reported before the Michigan State Medical Society two years ago. The first 100 intubations gave a mortality of 31, the second 100 showed 20 deaths and the third 100 18 deaths; being a total of 300 intubations (with the use of antitoxin) and 69 deaths. With two exceptions these operations were performed in private practice and for the most part among the ignorant, superstitious, foreign element of our city, whose children are given but little attention in sickness or in health. Two hundred and thirty-one of these intubated children have recovered. Of this number 8 have required "prolonged intubation," and in addition two cases from other operators have been referred to me for treatment.

The pathology and etiology of "retained tubes" include a consideration of traumatism during intubation and extubation, and traumatism while the tube is in position. The presence of pseudo-membrane, edema, superficial erosion, deep ulceration of the mucous membrane, cicatricial contraction, exuberant granulations, collapse of the cartilages, abductor inadequacy and paralyses are the usual causes. In certain cases one may ascribe the compression of the recurrent nerves to tuberculous ganglia, pleural thickening or some unknown neurotic phenomenon.

The admirable autopsy reports of O'Dwyer, Nicol, Bokay, Meslay and Ganghofner have thrown much light on our difficulties. The latter found four with erosion of mucous membrane among 42 intubated cases. Meslay reports a case of ulceration of the trachea and mediastinal abscess. Bleyer shows 1 per cent. of ulcerations in prolonged cases. Carr gives the details of an ulcer one-third of an inch long caused by the string. He also reports instances of ulceration through the anterior tracheal wall and cartilages. In this case a 3-4 tube had been used in a child 2 years and 8 months old. Bokay found 18 superficial and 3 deep ulcerations in 72 autopsies. The tube in one case had been removed at 24 and 48 hour intervals and the string left in. Avendano, on the contrary, performed 10 autopsies where the tube had remained for many days and found in one only a small loss of mucous membrane. The spasmodic ulcerous condition, or what the French term "the tubard," is characterized by numerous rejections of the tube. Bryant reports a case with three auto-extubations in fifteen minutes. Such cases may require special corrugated tubes or morphin in small doses. The short tube of Bayeux is subject to more frequent rejection than that of O'Dwyer on account of the enlargement at the cricoid ring where ulceration of the cartilages occurs in places. In such events the laryngeal nerve endings become exposed, thus rendering the reflex accident of auto-extubation very painful or annoying. The spasm of the intrinsic and extrinsic muscles of the larynx must be allayed by proper treatment applied to the sources of irritation, viz., ulcerations. This class of cases usually

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M. McClanahan, A. C. Cotton and H. E. Tuley.

present the phenomena of collapse of the larynx attending muscular inadequacy. A tube of correct size must, therefore, be placed in the introductor in preparation for this emergency before extubation is performed.

The diagnosis of the exact condition in the larynx is usually very difficult or impossible. There are a number of clinical evidences which are of great value, however, in differentiating and locating the trouble. Laryngoscopic examination is recognized as the ideal method, butamongyounger children in private practice it is found to be extremely difficult and unsatisfactory. Dangerous reflex spasm may also result from it. The history of unskilful operating or the use of a tightly-fitting tube is usually sufficient. F. L. Taylor's recommendation to use a tube in number next above the age of the child should receive sharp criticism. His report of 26 recoveries in 36 intubations following this procedure shows 22 tubes remaining in the larynx from five to eighteen days. The frequent obstruction noted in reintubation is due either to edema at the entrance of the larynx or subglottic erosion with attending edema. These conditions can be suspected from the difficulty encountered in introducing the tube. The indications of ulceration may be considered, first, as bloody expectoration following gentle extraction and continued pain over the larynx. Besides eroded black spots may appear on metal tubes, or calcareous deposits with disintegrated tissue from the points of contact with the ulceration. There may be frequent and continuous rejection of the tube, the development of a late hemorrhage or a gradually increasing dyspnea, differing from a spasm of the glottis. The prolonged presence of pseudo-membrane can usually be determined by the exfoliation of small pieces during the second week or by the development of reinfected areas elsewhere.

In the last 100 intubations I have had only one prolonged tube—a case of edema that responded to treatment in ten days and after the third extubation. Every case of intubation requires the most careful prophylactic treatment, and traumatism and pseudo-membrane as causes of prolonged tubes need not exceed 1 per cent. The early administration of sufficient antitoxin is of the greatest importance. Ten to fifteen thousand units without deleterious effects are reported to have been given by some observers, and the tendency to give a larger dosage of from three to five thousand units is very general. A minimum dosage of three thousand units in every laryngeal case, I believe, would prove efficient prophylactic therapy in cases of persistence of the membrane. Three cases of this variety occurred in my early experience. One required the tube nine days, another ten days, the third—a girl of 2 years and 9 months—expectorated laryngeal exudate for twelve days. She wore the tube seventeen days and required twelve intubations. In pre-antitoxin days Huber reports that sixteen days were not infrequent on account of pseudo-membrane. The statements of Quodfleig that not more than three intubations must be done on the same patient are therefore challenged. Experience in this last case showed me the great necessity for a large supply of tubes. My only No. 2 obturator broke at one of these operations, and in attempting to pass a No. 3 tube I nearly lost my patient. I subsequently had a case for instruments so arranged as to hold more than four complete sets of tubes, with all the necessary tracheotomy instruments.

The problem of the prevention of traumatism is more than half solved in the selection of a properly fitting tube. Fifty tubes are a good working number, and two sets of smaller tubes are essential to every operator. The greatest care should be exercised in cleaning the tubes, for if any roughness or other imperfections exist it may cost the life of a patient. Where pathologic conditions are suspected new tubes are found more satisfactory. The metal tube in prolonged cases is dangerous and should be discarded. Three common methods of extraction are presented: the string, expression and the instrumental. As extubation is more difficult than introduction, traumatism is frequently the result of the manipulation. The expression of O'Dwyer tubes is a dangerous practice and should be avoided. In private practice the string should be left in place if possible when there is an extension of membrane below the tube. Numerous modified instruments have been devised to make the operation easy and harmless, such as Dillon Brown's hook method and the electro-magnet of Collette of Antwerp, but the O'Dwyer instruments fill all the requirements when in careful hands. Unskilful use of the extractor and excessive pressure on the epiglottis with the finger may lead to edema of the soft parts or of the subglottic tissue or arytenoids, thus making reintubation necessary. Bleyer reports fifteen permanent lesions of the larynx from this cause.

The great importance of dispensing with the tube as early as possible is certainly recognized, but daily extubation with this object in view is impracticable in private practice. A safe general rule which I have found successful is to extract all tubes on the fourth day. A liberal dose of antitoxin twelve hours or more before intubation renders the success of this routine procedure almost certain.

Perfect quiet after the removal of the tube is of the greatest value. The application of ice cloths over the larynx and the use of the croup tent are not to be resorted to if quiet is to be sacrificed. A child difficult to manage is given a dose of paregoric or codein and phenacetin one hour before operation, which may be repeated if necessary. The child is not allowed to speak or cry, if possible, and with no recurring dypsnea during the subsequent two hours recovery will usually be complete. If reintubation is necessary after the sixth day a definite line of exact procedure and therapy can be outlined according to a diagnosis of the condition attending each case. When on the sixth or seventh day dyspnea suddenly returns and we have evidence of pseudo-membrane or we suspect a reinfection, 1,500 or 2,000 units of additional dosage will check its development, and the prognosis will seem especially good. In conditions of this kind and in paralysis and muscular inadequacy complicating diphtheria, large doses of strychnin are extremely valuable. In many cases efforts to dispense with the tube may be made at two or three day intervals. Rubber tubes may be used, and at reintubation the next smaller size may be inserted in order to change the points of pressure. Having determined as accurately as possible the location of the eroded surfaces, an alum ointment (12 per cent.) may be applied to the surface of the tube and intubation again performed. The string protected by adhesive plaster can be left, to insure the utmost gentleness in extubation.

Although the treatment of these cases is attended continually by annoyances and difficulties that are trying to the surgeon, the results are exceedingly satisfactory. The statement of Goodall of England that frequent expulsion of the tube is an indication for tracheotomy, the observations of Sevestre and Eschevick that tracheotomy should be performed if the tube can not be removed within a week, and the opinions of many German and

French operators that tracheotomy must be performed if the tube can not be dispensed with after three intubations, are mentioned to be condemned as unjustifiable and unnecessary procedures. "Tracheotomy is the worst possible thing that can be done," said Dr. O'Dwyer, "for healing of the ulceration is promoted too rapidly after the operation, and a subglottic stenosis results."

Recent literature from Italy and France confirm our own methods. Dr. Tanturri of Naples reports in detail a most interesting case of prolonged tube. Forty intubations and 136 days were required. Alum and ichthyol gelatin with the O'Dwyer tube proved successful. In conclusion, he says that the perforated tube of O'Dwyer is of priceless service in exuberant granulations situated in the region of the cricoid, and that ichthyol is the best medicament. Roe of New York State reports three interesting cases following simple laryngitis with recovery, the longest of nine weeks' duration. Louis Fischer's plan, unknown to me until recently, carries out most efficiently the same suggestion as O'Dwyer's one case. He used 10 per cent. alum or ichthyol-gelatin. The objection to gelatin is the greater difficulty of its preparation, and, like vaselin, it has a low melting point, but mixing with agar any desirable melting point can be obtained.

The method of direct medication to the larynx in cases of prolonged tubes deserves a more extensive use. Argyrol, menthol or resorcin preparations should give good results, and adrenalin applications are recommended for cases of edema. It is thus possible to treat the larynx in all cases requiring reintubation. Of the ten cases of prolonged tubes which occurred under my observation three were caused by persistent pseudo-membrane; two, of ten days' duration, were caused by edema at the entrance of the larynx, and five were necessary on account of subglottic or other laryngeal erosions or ulcerations.

Although some observers report to the contrary, the prognosis in this country would seem very good. The alum treatment was successful and all recovered but one. The fatal case, 2 years of age, died on the seventeenth day after intubation. Autoextubation without the knowledge of the mother occurred while she slept, and when the mother awoke the child was dead. The tube had been out several hours the previous day, the child's strength was good and the case seemed to be progressing favorably. The fact that hospital treatment is absolutely necessary for these cases is recognized, but the parents of the children of our foreign element stubbornly refuse to be separated from their children. Less than a dozen of my 300 intubations, including one case of prolonged tube, have received hospital care or the services of a trained nurse.

The two most interesting and difficult cases I report in detail as follows:

CASE 1.—M. B., aged 5 years, had been treated 48 hours for spasmodic croup when Dr. McColl took the case, Jan. 30, 1901. The true condition of diphtheria was recognized immediately and a consultant called. Intubation was performed with considerable difficulty, as the tube was too large. After five days this was extracted again with difficulty. Labored breathing began immediately and reinsertion of the tube was necessary. On February 11 a third extraction was made. The dyspnea gradually returned, and on the 23d the case came under my observation, when intubation was required, and a number three tube coated with alum and vaselin (12 per cent.) was used. A tough ring of cicatricial tissue could be felt at the entrance to the larynx and it was evident that a subglottic stenosis existed. After a series of auto-extubations the parents allowed the child to be removed to the hospital. A No. 2 tube was inserted and the string left in. Three applications of alum and vaselin at three or four day intervals, together with tonic medication and steam sprays succeeded, and on March 13 the tube was permanently removed—a period of forty-two days after the first operation, during thirty of which the wearing of the tube was necessary. The two weeks after extubation was marked by considerable dyspnea coming on each evening, but the croup tent and the use of anti-spasmodics were sufficient to palliate the symptoms. At the present writing (two years later) the child is in perfect health.

CASE 2.—Eva B., aged four years, patient of Dr. O. T. Toepel, was intubated June 20, 1899, for stenosis from laryngeal diphtheria. As a No. 4-year tube was too large, the next in size was introduced, and 1,500 units of antitoxin given. Thirty-six hours later the membrane had extended below the tube, and a hurried extubation was necessary. A longer and larger No. 4 tube was then introduced, and the case progressed favorably. Extubation was attempted on the fourth day, but it was necessary to quickly replace it on account of dyspnea promptly returning. Extubations were attempted at two and four day intervals. Three treatments were given the larynx by applying alum ointment along the tube before operation. This method was successful on the twenty-third day, and the child made a perfect recovery.

When these measures fail we have the various modifications of the tube to depend on. The granulation or ulceration tube can be made with a larger (or built up head) and a lower and broader swell. The lines of contour can be changed so as temporarily to remove the pressure from any injured portion of the mucous membrane.

Successful instances of the use of these tubes and retained for some months are reported by O'Dwyer, Northrup and Rosa Engelmann.

In conclusion I would make the following summary:

Cases requiring a tube more than six days should be classified as prolonged.

Rubber tubes only should be used.

Liberal doses of antitoxin are required in cases due to reinfection or persistence of the membrane.

Large doses of strychnin are of value.

Smaller or modified tubes coated with alum ointment or alum gelatin should be introduced at each reintubation.

The string may be left in place with advantage in many cases.

When these measures fail, the "granulation tube" may be used.

Tracheotomy is never indicated.

32 West Adams Avenue.

DISCUSSION.

DR. CHARLES G. KERLEY, New York—I have seen only one case of prolonged retention of intubation tubes in my own practice, and two cases in the practices of others. However, my general experience with intubation leads me to indorse everything that has been said in this valuable paper. I do not think that retained tubes are at all necessary. If the rubber tube is used, if it fits, if it is put in and taken out by one who knows how to do it, there should be practically no cases of prolonged retention of the intubation tube. In introducing the tube force must not be used; when it is required it means that the tube is too small, and that laceration will occur. A properly fitting tube will pass in with practically no force. I do not find extraction at all difficult, although I make use of the ordinary extractor of the O'Dwyer set. The finger must, of course, be used as a guide. It is a temptation, I admit, to leave the string, but in older children there is great danger of the child getting hold of the string and pulling out the tube. The only use of the string is in the event of membrane loosening below the tube, making it possible for the tube to suddenly become plugged, thus requiring its immediate removal by the nurse or other attendant.

I think in the future we shall hear much less of these cases of retained tubes, because we have learned how to use antitoxin. I never give a laryngeal case a smaller dose than 3,000 units. The last case I had was one in which I was called late in the attack, and the child had been treated for five days for ordinary croup. Suddenly laryngeal obstruction developed, and I was hurriedly called. I gave the child 1/50 of a grain of strychnin and 1/100 of a grain of digitalin hypodermically before daring to insert the tube. As soon as the tube had been introduced I gave it 3,000 units of antitoxin, and in the course of the next sixteeen hours, 6,000 additional units.

The intubation tube was removed on the fourth day, and a re-introduction was not required. The fourth day is the time, in my opinion, to remove the intubation. I fully agree that tracheotomy has no place alongside of intubation. In my own case of retained tube I believe the cause was an abductor paralysis, for I was unable to find any lesion on careful examination; there was only obstruction to inspiration.

DR. EVERETT J. BROWN, Decatur, Ill.—The first case of intubation which I did was in a patient six miles from town, a boy of 7 years, who had been given up by two other physicians. I inserted the tube, giving complete relief. The tube was left in until the sixth day, and the child recovered without any return of the dyspnea. I noticed in a Vienna clinic that they took out and inserted the tube daily, but I was uncertain whether this was considered desirable for purposes of cleanliness or for purposes of clinical instruction. Recently I was called to do an intubation on a child of 5 years who was nearly comatose. I failed to introduce the tube after three attempts. On the fourth attempt the tube was coughed up after a few minutes, and with it a thick membranous cast, which extended down even to the finer ramifications of the bronchi. I had a photograph taken of it, which will soon be published. In this case the obstruction was as much in the bronchi as in the trachea. The child was at once relieved after coughing up this cast, but it died of toxemia, and not of dyspnea, about twelve hours later.

DR. B. R. SHURLY, Detroit—I wish to emphasize the method of applying alum and vaselin to the tubes. So far as I have been able to ascertain, this method is comparatively unknown to those who practice intubation. When there is difficulty in extracting the tubes this method is of the greatest value. It has been used in Italy in one or two cases, and Dr. Louis Fischer has also tried it. This suggestion was thrown out in the last paper written by the lamented Dr. Joseph O'Dwyer. I simply advocate leaving the string in those cases in which the membrane is below the tube, or in those cases in private practice when it is impossible to reach the child quickly in an emergency. I think the frequent intubations and extubations referred to as occurring in Vienna hospitals were entirely unnecessary, and they appeared to me to be done largely for purposes of clinical demonstration.

CONTINUED FEVER—NEITHER MALARIAL NOR TYPHOID.*

T. J. HAPPEL, A.M., M.D.
TRENTON, TENN.

It may seem that the subject of continued fever is becoming too common in our meetings to merit any further time or discussion, but, so long as we are met with the *ipse dixit* of some bookmaker, that there are but two types of continued fevers, and that all such fevers must be classed with one or the other, in fact must be either malarial or typhoid, then those of us who do not accept any such dogmatic statements as necessarily true, have a right to give our reasons for our dissent. Our medical brethren in the north, as a rule, contend that every continued fever is either typhoid or malarial, while in the south many of us are sure that we have a third fever, which merits a careful study, the mortality of which is so slight that opportunities for postmortem study have been almost *nil*.

The blood and secretions have been examined microscopically and chemically so far with negative results. A sufficient number of examinations have been made of the blood to show that it does not respond to Widal's test, nor does it show the presence of the *Plasmodium malariæ*. In none of these cases has the estivo-autumnal parasite or the *Bacillus typhosus* been discovered, yet we are told by the bookmakers that the technic was faulty; that the examinations were improperly made. While not prepared and not competent to make any of these examinations, or to apply properly any of the tests in these cases, I have too much confidence in the ability and honesty of the laboratory workers who have made these reports to doubt their correctness. (Just at this point I would offer this suggestion, that no specimen sent to a microscopist or chemist should be accompanied by any clinical history of the case, to avoid the warping of the judgment of the examiner. He should be requested to examine the specimens sent for the evidences of malarial or typhoid fevers, and to report the result of his examination.) We can more often find what we look for than the unknown or unexpected; hence, I say that the clinical history of the case should be withheld.

The teaching of the present day, as pointed out by the learned Dr. Jacobi in an address at Saratoga before one of the Sections of the American Medical Association, in which he spoke with no uncertain sound, does not develop the skilled clinician. The bedside study of diseases has been relegated to the background and the student is impressed with the idea that the microscope will tell him positively all about his case. In many of our diseases the microscope is as yet powerless. One laboratory worker reports and describes a specific germ for a disease, and another soon after reports one entirely different.

In this fever to which I invite your attention the microscope fails to show the *Bacillus typhosus* or the *Plasmodium malariæ*. Reference was made in a former paper to the fact that a number of skilled laboratory workers had investigated the secretions and blood, both microscopically and chemically; by one in more than one hundred cases, and by another in thirty-eight cases, with the same result in each, both asserting positively the absence of anything distinctive of either typhoid or malarial fevers. In numerous other instances the same results have been obtained by others. Yet we are told that Dock of Ann Arbor has proven conclusively that the cases of so-called continued malarial fever in Texas were cases of true typhoid fever, and Dr. Osler asserts that he feels sure that all the continued fevers except those of thermic origin will yet be divided into but two classes, malarial and typhoid, which position is equivalent to asserting that our microscopists who have reported otherwise were not qualified to properly investigate the etiology of these fevers and that our chemists had not skill enough to apply the tests necessary in that part of the laboratory work. His argument is along this line:

> Typhoid fever in Baltimore and Philadelphia, where malaria exists, is not essentially different from the same fever in Montreal where no malaria is found; hence the other continued fevers in the south where malaria exists and where typhoid fever is rarely found must be true malarial fever.

This can not be said to be a first-class argument. A fever that is totally distinct in every respect from the

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

malarial or typhoid fevers except one, viz., duration, can not of necessity be one of the two types. Not many years ago we recognized only two types of the eruptive fevers: measles and scarlet fever; yet recently measles has been divided into rubeola and rötheln, and roseola is certainly distinct from either, and within the last two years an effort is being made to divide scarlatina, as it had been known, into two distinct diseases, each having its own *causa causans*.

Our boards of health have not yet accepted the doctrine of a disease resembling variola, pseudo-smallpox, having the same relation to variola that rötheln does to rubeola, and the new differential of scarlet fever does to true scarlatina. This effort on the part of those standing high in the councils of medicine to decry anything new not originating with themselves does not tend to encourage individual research. The impetus to medical and surgical investigation along many lines has often been given by the country practitioner or surgeon, as evidenced in the cases of Marion Sims of Alabama and McDowell of Kentucky.

I lay no claims to the discovery of a new fever, but I do take the position that we have here in the south a continued fever that is neither typhoid nor malarial.

In a former paper, I referred to a number of such cases treated by me in the last ten years, and since that paper was written a number of others have been under my care, and very favorable opportunities have been seized on to study these cases at the bedside. The conclusions have not been verified by any autopsies as all of them have recovered. Since July, 1902, I have treated six cases (a total of about one hundred cases), lasting three weeks in the shortest to five in the longest. In each one of these cases the diagnostic points were strongly in evidence. The first case was ushered in by a cold stage, not the chill of malarial fever, but rather the algid stage of la grippe followed by a slight rise of fever, and on the following day at about the same hour more rigors with intense headache and a temperature of 104. The parents, supposing they had an intermittent fever with which to deal, had given calomel, followed by quinin in full doses until the daughter was cinchonized, as evidenced by deafness, etc. When called on the fourth day, I found a normal pulse, profuse perspiration and, while the parents thought her free from fever, a temperature of above 104, no vomiting, no special complaint except headache. Concluding that I had a malarial attack to deal with, I increased the number and size of the doses of quinin sulphate so as to give between 25 and 30 grains before the time for the next paroxysm on the following day, with directions to continue until my return in 48 hours. My next visit showed no effect from the quinin except to increase the deafness and to disorder the stomach and destroy the appetite. I found pulse 78, temperature 104, no tympany, no engorgement of the liver or spleen, no broad flabby tongue, no jaundice, no special complaint about anything except headache. I abandoned the further use of quinin, and prescribed salicylate of soda and carb. guaiacol as follows:

℞. Sod. salicylat. ..... ʒiii
Guaiacol carb. ..... ʒi
Milk of magnesia ..... ʒii
M. et ft. Mist. S. shake well. Teaspoonful every four hours.

A mixture of aconite and gelsemium was prepared to aid in reducing temperature, and for the same purpose frequent sponging with tepid water was directed. On my next visit there had been two cold stages in each 24 hours, but the temperature had not risen above 103. The treatment as outlined above included free and frequent spongings with tepid or cold water, as preferred by the patient, and when the temperature resisted these measures and persisted in remaining up to 103 degrees, 5 grains of acetanilid to reduce, but not to be used if it could be avoided. Only 9 grains of quinin sulph. each day were given until the case fully recovered, which required four weeks from date of going to bed. In this case there were two well-marked rises of temperature in each 24 hours. There was no anorexia, and not a single point of resemblance in the case to typhoid fever.

In one of my other cases the attack was ushered in, or, rather, preceded by an attack of irritation of the alimentary canal, amounting to almost a case of enteritis, caused by the immoderate and excessive drinking of ice-cold lemonade at a Sunday-school picnic. For several days all symptoms were masked by the frequent small, griping, mucous discharges from the bowels, the excessive thirst, tympanitic distension, and an inability to retain anything taken per os. As these symptoms subsided, leaving the whole abdomen tender, the tongue, which had been red and small and long, returned to its normal state, the thirst became less, and the rises in temperature, in spite of all that could be done, were three in 24 hours. Quinin per rectum, after a failure to prevent these exacerbations per os, had no effect on the fever. In this case I was not content to use one form of quinin alone, the sulphate, but resorted to the bi-sulphate, and later to the salicylate. At the end of ten days, no impression having been made on the course of the disease by the antimalarial remedies used, they were abandoned, and the guaiacol-carbonate and soda salicylate of the first case substituted, and under this course the patient was carried through a sickness lasting five weeks, to be followed in two weeks by a relapse from imprudent eating. This lasted two weeks.

The third case lasted four weeks, receiving thorough antimalarial treatment for one week, which was abandoned as useless, and the medicines referred to in Cases 1 and 2 substituted, supplemented later on by a mixture of tr. iodin and Fowler's solution every four hours. The temperature chart showed four rises of temperature in each 24 hours, and later on three, then two, and then one. In this case, from the effect of quinin used during the first week, the digestive organs were weakened so that only malted milk could be retained for a few days, though a desire for food was ever present, and the patient, a female, aged 10 or 12 years, never failed to report herself feeling better, and when her temperature would rise to 103 or 104, the pulse rate was never higher than 90. There was never a dry, harsh skin, never bilious vomiting, never nausea except that which resulted from the use of the quinin the first week. She was always ready to eat, but never thirsty. All the secretions were normal, the bowels generally acting once every 24 hours. At one time she was allowed by her mother to eat sardines, with no unpleasant sequences. At the end of the fourth week the fever ceased, terminating, as shown by the chart, by lysis. In this case there were no profuse sweats as there were in the first and second cases.

Case 4 was a boy, aged 8 years, just on the opposite side of the street from Case 3. It was very mild, showing only two rises of temperature in 24 hours. This patient was saturated to deafness with quinin, which was then laid aside except 6 grains per day, and the guaiacol-carbonate and soda mixture alternated with the iodin and Fowler's solution used throughout the

case. On the twenty-first day the fever terminated by lysis. This patient was hungry from the time he was put to bed until he was dismissed. At no time was there any derangement of any of his secretions. With his light diet he became constipated and was given cascara two or three times each week. During the second week he was given four doses of calomel, gr. 1/10.

Case 5 was a repetition in every respect of Case 4. These cases are added to a long list of similar cases already treated by me, with only one death, due to congestion resulting from a disobedience of directions. While a few of the cases have lasted six weeks the rule is recovery in from three to four weeks. We do not expect, except in very young children, recovery before the end of the third week, and my invariable answer to questions of the probable duration of the disease and the prognosis is that they will recover, but not before the expiration of 21 days from the date of going to bed.

In my last case treated (November), the temperature, after dropping the quinin, slowly but steadily decreased each day, until on the eleventh day from going to bed it dropped to normal and did not rise above 100. This case appeared to be a duplicate of Case 5. But the slight rises of temperature alone and the little difference between the daily maximum and minimum point is no indication of the duration of the attack, several of such cases having lasted from four to six weeks, and in one case especially referred to in one of my former papers on this fever, after continuing for three weeks with a maximum temperature of 101 to 102, during the fourth and fifth weeks there were daily ranges from normal to 104 and over. These cases are the ones we expect to terminate by crisis with profuse sweats.

The cases of this season have demonstrated the fact most conclusively that quinin will not cure this type of fever. I have used it in varying doses per os and per rectum. In none of these cases was the use of it discontinued until decided deafness was produced, no attention being paid to any of the other symptoms of cinchonism. I have not used any of the quinin salts in from 20 to 40 gr. doses, never do, but have repeated in from 3 to 10 gr. doses until the effect was self-evident, and then have maintained this effect for from three days to a week and in some cases to ten days.

Reference has already been made to the use of microscope and chemical investigations in these cases, hence I will devote no further time to this branch of the subject, not being able to speak *ex cathedra* myself in the matter. I desire, however, to emphasize the point of difference from a clinical standpoint, and permit me to add that where the bedside study of a case teaches plainly one thing and the work of the laboratory another, I, for one, would strongly incline to the teachings of the sick chamber. It has been demonstrated time and again that the laboratory worker has agreed with the clinician in this fever, and yet the question of competency has been raised; while no question is raised in the case of other workers in the laboratory when they have discovered, or thought they have found the micro-organism for which they were looking. These cases have not, then, been ushered in, as a rule, abruptly by a chill, but have had usually for a few days or a week prodromes of malaise, then rigors, sometimes a slight chill, followed by a slight rise in temperature, which does not generally attain its maximum for from three days to a week. While this fever presents marked remissions, for the first week the remissions are not so decided in the second week, but are more so in the last week, amounting to intermissions with profuse sweatings. The chills, or cold stages, are accompanied by aching of sometimes one set of muscles and sometimes in all, resembling in that respect la grippe. After a day or two all pain ceases, and the patient complains of nothing. The remissions in this type of fever vary from one to four in 24 hours, and may be made more marked by sponging with tepid water in all cases by aconite and gelsemium in a few and by the coal-tar derivations in almost all of them. As a rule, sponging produces a condition of euphony and the patient never objects to its use.

There is no nausea and vomiting; never bilious vomiting, no jaundice, no clay-colored stools, no diarrhea, and, if any departure from the normal in this respect, constipation; no tympanites, unless it be due to some imprudence in eating; no tenderness over the abdomen; no rose-colored spots; no marked enlargement of the spleen or liver, unless there has been a history of malaria preceding; no anorexia, but, on the contrary, in many cases a desire for food all through the sickness; no broad, dry, flabby tongue, with its yellow pasty coating, but, as a rule, a tongue nearly normal in every respect, and when coated it is thin, of a light color. We have, in none of these cases, the pointed, narrow, dry, fissured tongue, with its red edges and dry, coated, and frequently cracked center. The tongue never bleeds, in fact the rule is all typhoid and malarial appearances are absent from the buccal cavities and the rest of the alimentary canal. The digestion is rarely impaired for food suitable for the sick, though I have noted abdominal distension when solid foods have been administered or allowed. There is no mental hebetude; in fact, generally the brain is not affected at all and ordinary business matters could be attended to by many of these patients with their usual business acumen. We never have any low muttering delirium as in typhoid fever, nor the active symptoms of malarial fever. The facies of the patient is normal, though he may be thin from loss of flesh attendant on the long drawn out fever. The muscular strength is not impaired as in typhoid fever, but its loss is in proportion to the length of the attack and heighth of temperature. In one patient sick six weeks, with a temperature reaching 105 daily for nearly two weeks, the loss of weight was slight, but the muscular tone was much impaired but was rapidly regained.

That these cases are probably toxenteric, as claimed by Dr. J. A. Witherspoon of Nashville, is evidenced by the fact that when relapses have occurred, in my practice they could be traced to imprudent eating. In no case of the many treated have I ever seen any tendency to epistaxis, though in some persons who were predisposed to tamper with their nasal organs, a few traces of blood have been noted in the secretions blown from the nose. The kidneys have acted, as a rule, normally, the quantity of urine being diminished where the skin has acted too freely. We have no dry harsh skin in this fever as in typhoid fever, nor is sweating any evidence as in malarial fever of a decrease in temperature, the skin in this fever being frequently bathed in perspiration when the temperature is at its maximum.

One of the most marked peculiarities of this fever is the disproportion between the pulse rate and the temperature. The ratio is frequently inverse, the pulse beating at from normal to 90, with a temperature of 103 to 105 or even higher, and the same may be said to be true in regard to the temperature of any exposed portion of the surface of the body. The hand applied to the pulse and then to the forehead would lead anyone not

using a thermometer to say that there was a perfect freedom from fever. This condition of things has been reported to me time and again, and yet when the thermometer was used in the mouth or axilla a high temperature was clearly shown. The hand applied over the bowels or to the back under the clothes and cover frequently shows fever. In these cases, no proper nursing can be done without the use of the thermometer every two hours, and a record is required to be kept in every case, with, however, a verbal direction not to disturb the patient when soundly sleeping. I might refer to the fact that it has been my experience that the nearer a direct proportion between pulse and temperature, the more confidently is a termination by lysis to be expected at the expiration of 21 days, and vice versa. In those cases of indirect ratios the termination is more likely to be by crisis and profuse sweating. In this class of cases, when the fever begins to intermit, strychnin is demanded. I might consume time indefinitely on the subject, but my time is up.

TREATMENT.

As to treatment, a few words. As soon as satisfied that the cases are not malarial, which should be determined in four days, quinin should be abandoned or used as a tonic in 3 gr. doses. I have obtained my best results by alternating the following prescriptions for an adult:

℞. Guaiacol carb. 3ii
Sod. salicyl. 3vi
Bismuth. lact. ..... ℥iv
M. Sig.: Take one teaspoonful every four hours.

℞. Tr. iodin. 3ss
Liq. potas. arsenit. 3i
Aquæ ..... ℥iv
M. Sig.: Shake. Teaspoonful every four hours. Alternate with the first mixture.

All symptoms are met as they arise, but unless some idiosyncrasy is manifested by the patient and the temperature runs high, these two prescriptions are kept up regularly night and day, but where the grade of fever is low they are usually omitted at bed time, say 10 p. m. I have used many intestinal antiseptics in treating this fever, but have had the best results this year from the above course.

The temperature is reduced by the free use of tepid or cold water, allowing the patient to choose.

The diet is liquid or semisolid, buttermilk being preferred to anything else when the patient can use it.

SOUTHERN FEVERS.*

WILLIAM KRAUSS, PH.G., M.D.
MEMPHIS, TENN.

In assigning this subject to me, our secretary said he wanted to show that some missionary work on the subject of fevers in the Mississippi Valley was being done, despite the controversies one sees about slow, continued, typho-malarial, and other fevers. With this idea of the scope of the paper, fevers of sepsis, tuberculosis, rheumatism, syphilis, etc., have not been given a place.

The cases presented are to be looked on as types of a number of cases seen by the author, and are believed to serve the purpose better than an elaborate discussion for which we have no time. None of the histories are complete, but enough is offered to make the point intended.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

1, ACUTE ESTIVAL FEVERS; 2, CASES WITH AUTOPSIES.

CASE 1.—W. B., male, white, aged 54, was brought to St. Joseph's Hospital in July, 1900, in an unconscious condition. From others it was learned that he was a passenger on a train coming to Memphis, and was suddenly taken with what was described as "congestion"—a term very much in vogue to denominate sudden fevers usually terminating in death. His temperature on admission two hours later was 108 F. The notes of the attending physician state that ice baths, subcutaneous injections of antipyrin and quinin had failed to bring about a change, and he died in six hours without ever regaining consciousness.

A blood examination had not been ordered, but the antemortem diagnosis read "pernicious malarial fever." The following from the necropsy report is of interest:

Autopsy five hours after death; rigor mortis; body of a very plethoric man; capillary stasis; ecchymosis; incision over calvarium bleeds freely; excessive hyperemia of encephalon; blood smears taken. Abdominal viscera pale, no marked changes; pleuræ free, lungs hyperemic; heart very firm, right ventricle full of dark fluid blood; smears from this also; no plasmodia in either. Postmortem diagnosis, sunstroke.

CASE 2.—Colored man, aged about 45; arrived at city hospital comatose in August, 1900. Attendant's notes showed rectal temperature of 107 F. on admission; plasmodia in blood. Was packed in ice, quinin and saline infusion subcutaneously; slight reaction; death next morning.

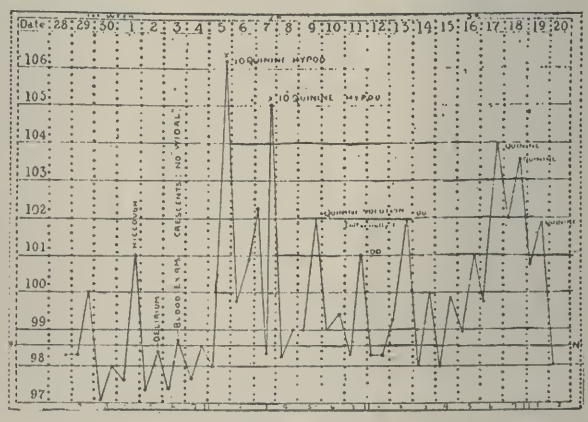

Chart 1, case 3.

Autopsy: Marked hyperemia of all the organs; heart contains thrombi which are nearly white.

The tissues and blood were taken to author for microscopic examination.

Smears from lungs and brain contained estivo-autumnal parasites, no crescents; splenic blood not fit for examination. Microscopic sections showed marked pigmentation in liver, spleen, kidneys and lungs. Pigment is siderin, not melanin. Very marked fibrous endarteritis, especially of the coronaries, doubtless syphilitic. Tissues had been in formalin very long and efforts to stain parasites in the sections proved unsatisfactory.

These two cases are reported as different comatose fevers with very similar symptoms. If the attendant of the first case had made a blood examination he would not have fallen into the error of giving quinin to a patient with sunstroke—it was a serious mistake.

II. CONTINUED ESTIVAL FEVERS WITH DIARRHEA, 2 CASES, WITH ONE AUTOPSY.

CASE 3.—J. M., aged 26. Admitted to St. Joseph's Hospital Sept. 28, 1899. Had been sick at Little Rock, Ark., with dysentery for a week; had had vomiting and daily chills. On admission showed abdominal tenderness, slight tympany, gurgling in right iliac fossa; spleen enlarged and tender; tongue dry, red and hard, with fissures; low delirium at times. The accompanying temperature chart completes the history, but the record for the first five days is not correct,

as it was found afterward that he had nocturnal chills and exhibited much prostration in the mornings. A physician in consultation insisted on its being typhoid. The blood analysis appears on the fever chart; he had the malarial leucocyte count, estivo-autumnal parasites, crescents, no Widal reaction. The treatment was antimalarial, salines for the dysentery. He was discharged cured at the end of four weeks. His paroxysms being nocturnal, they had been overlooked and the accompanying dysentery helped to produce the typhoid symptoms. Heroic quininization changed the picture.

The temperature chart and blood examination saved this case from being classed as typhoid fever, and death would have been the result.

CASE 4.—(Record taken from the Reports of the Marine Hospital at Memphis.) The writer saw the patient several times and assisted at the autopsy:

J. F., colored; native of Louisiana; admitted to the United States Marine Hospital at Memphis Dec. 26, 1896, and died Jan. 3, 1897.

History.—Patient was a well-developed and healthy-looking colored boy. He had been sick for four days with chills and fever. Initial chill came on in the evening and was very severe; had a similar chill every evening up to day of admission. His bowels were very loose from the first. Discharge watery and preceded by pains in the abdomen. Temperature on admission was 40.5 C. Pulse poor; tongue round and flabby, clean and red on edges and moderately furred in center. Neither liver nor spleen noticeably enlarged. Was given tincture digitalis on admission and was ordered quinæ every four hours with bismuth and mixture for diarrhea. His

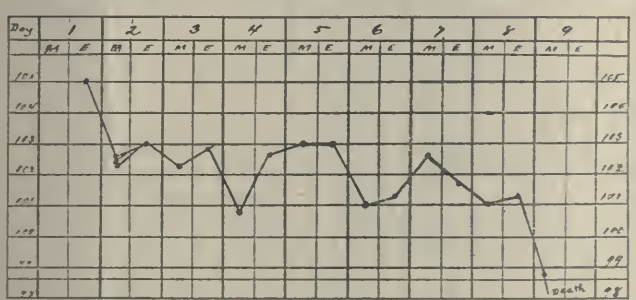

Chart 2, Case 4.—J. F., U. S. M. H., Memphis. Temperature transposed to F. scale. Remittent fever, with diarrhea, perforation and death. Prodromes: Chills daily, 4 days; one on admission; parasites in blood.

temperature on the morning of the 27th was 39 C. and pulse 90; bowels loose but less so than on preceding day. His blood showed a large number of very small extra-corpuscular "rosettes" and some granular bodies. The segmentation in rosettes was not as distinct as usual. On admission the diagnosis of intermittent malarial fever was made to conform to official nomenclature, but the blood examination showed at once that the disease was estivo-autumnal, or, as the nomenclature has it, remittent fever. The possibility of a mixed infection was considered but abandoned. There was an entire absence of tympanites, gurgling and iliac tenderness. The stools were more watery and paler than typhoid stools, but still quite suggestive of typhoid. While the malarial nature of the case was clearly established, still the fever was a hard one to classify as to the kind of malarial fever present. The history from onset to admission pointed to a double tertian or to the variety of estivo-autumnal fever marked by quotidian paroxysms.

The appearance of the rosettes and the temperature curve for the first four days indicated the quartan type of estivo-autumnal fever, while the subsequent temperature curve showed regular tertian remissions. His diarrhea yielded slowly to treatment, declining by the 31st to two passages a day. On the 30th his blood showed both intra- and extra-corpuscular, small hyaline bodies, and a few large and actively motile pigment grains or blocks—two or three to each body. The next day only a few extra-corpuscular pigmented bodies could be found. His mental state from about the third day became rather foggy—a fairly typical typhoid state in fact.

On the 1st of January, the sixth day from admission and the tenth since onset of disease, he had several severe attacks of colic, and these recurred on the 2d. On the night of the 2d his pulse failed rapidly, tympanites developed, and it became evident that he had sustained an intestinal perforation. He died at 10 o'clock on the morning of the 3d, just twelve days from date of first attack.

Necropsy, twenty-four hours after death. Body fairly well nourished. No scars. Calvarium not opened. Lungs normal except for slight congestion. Pericardium contains about 200 c.c. of fluid. Heart rather small, but otherwise normal. Liver, spleen and kidneys normal in appearance and size. Intestines showed general fibrinous adhesions. About 250 c.c. of fluid present in abdomen. The ileum presented a large number of follicular ulcerations. These ulcerations were all opposite to the attachment of the mesentery. Peyer's patches were not at all involved. The mesenteric glands were not enlarged. Two perforations were present—one 4 cm. from the ileocecal valve and the other 12 cm. There were several ulcers, in which the coats were eroded down to the peritoneum. At about 20 cm. above the ileocecal valve there was an area about 2 by 4 cm. where the entire mucous membrane was eroded. Sections taken through the ulcers showed a typical follicular ulcerative process and an entire absence of any of the microscopic appearances of characteristic typhoidal ulcers.

The ulcers were small, funnel-shaped, less than 1 mm. in diameter, with elevated edges; the perforations were about 2 mm. in diameter and closed by fibrinous exudate. Dr. Young and I discussed the Widal test, but this was in its infancy; neither of us had any cultures of typhoid on hand, and Johnston's dried blood method was as yet unknown; typhoid fever is, of course, not scientifically excluded. We both wanted to believe it was typhoid fever; it was between Christmas and New Year, but the blood and postmortem evidences were against such a diagnosis, and it was reported as a case of remittent fever.

III. CONTINUED FEVERS WITH CONSTIPATION, 2 CASES.

During my term of service in the summer of 1899 at St. Joseph's Hospital I had 248 cases of fever, and of this whole number there were only 3 in which there was a question of diagnosis; one of these is reported above. During 1902 I was interested in 2 cases, which follow:

CASE 5.—O. G., aged 19, male, drug clerk; had had intermittent fever a year ago; malaise this time for several days, followed by catarrhal bronchitis. Seen first by Dr. Baldwin (to whom I am indebted for this history) on Oct. 26, 1902. Provisional diagnosis, la grippe; salines and salicylates administered; remission on second day, rise on third; cinchonized for three days. Temperature during first week, morning 100 to 101.5 F., evening 101 to 102, pulse 80 to 85. Dried blood spreads brought to me November 2 showed intracorpuscular estivo-autumnal parasites, about half grown, no crescents; infected cells generally crenated and small. Leucocyte count of 300 cells: small lymphocytes, 9.3 per cent.; large lymphocytes, 30.3 per cent; polymorphonuclear, 58 per cent.; eosinophiles, 1.3 per cent.; basophiles, 1 per cent.; a few microcytes and small nucleated forms, phantom cells and polychromatophiles. No Widal reaction in any dilution. He was thoroughly quininized again without visible change, and after another week malarial infection was still present; no Widal; small lymphocytes, 20; large lymphocytes, 14; polymorphonuclears, 64; eosinophiles and basophiles, each 1 per cent.

Pulse still 85 and good volume, now slightly dicrotic. Temperature runs from 100 to 103 without change in pulse. This time he was given 90 grains quinin hydrobromate in 24 hours; it seemed to have the effect of running up the fever, for he had 102 in the morning and 104 in the afternoon following, and for four hours there was intestinal hemorrhage, at first slightly clotted, then fluid and carmine red; there were no piles. Cold sponging was followed by a fall in fever

and profuse diaphoresis. The fever now gradually declined, reaching normal on the 32d day of the disease.

There was marked tendency to constipation throughout, combated by salines, and when these were suspended some tympanites would develop. Nose bleed once in the first week; a few petechiæ present once, but rather persistent; subsultus once, early; mental hebetude at times. Entire course mild and marked by very slow pulse. Widal reaction constantly absent.

CASE 6.—This patient took to his bed June 14, 1902, and was removed to a private room at St. Joseph's Hospital on the 16th. The previous history was that of malaise for a week, with gradually rising fever. The attending physician found estivo-autumnal organisms and pigmented leucocytes, and gave several intragluteal injections of quinin bimuriate with urea, 0.5 gram each in 10 c.c. of water at six-hour intervals. There was albuminuria with casts and gradually aggravating oliguria during the first week. Renal and frontal pains were constant and troublesome symptoms. There was obstinate constipation and intestinal paresis throughout. The patient could not bear cold to the surface, even icebags produced local neuralgia, and the temperature was reduced with thermol when it got near 104; for this reason the fever chart has no value.

At the end of the first week in bed, no blood evidences of malaria being present and fever still persisting, several trials with the Widal test were made, but without result. The diagnosis of paratyphoid was suggested by one consultant, but no cultures were obtainable. The fever definitely subsided at the end of three weeks without further resort to quinin.

This patient was seen by three very competent practitioners with all the resources of modern medicine at their command, yet one positively asserts that it was a case of malarial fever and proves it by his slides; the second is equally as certain that it was typhoid fever, despite the failure of the Widal test, and the third, who is our honored secretary, modestly suggested that it was paratyphoid. The writer's own opinion is not worth much, since he was the patient. A very complete history was taken, but it throws no light on the case.

During the summer of 1900, 26 cases with history of acute malarial fever were admitted to my service at St. Joseph's Hospital, none of which received any antiperiodic treatment after admission. The blood was examined in 11 without showing infection. They were held to await further recrudescence of the paroxysms, but the fever gradually subsided. They were booked as postmalarial malaise. Here is the history of one:

CASE 7.—L. F., female, aged 24, white, married. Lived in St. Francis bottom; admitted June 10, 1900, with history of tertian chills. Temperature on afternoon of day of admission 102 F., pulse 110 and small. Liver and spleen enlarged. Blood analysis next morning: reds, 3,640,100; hemoglobin, 70 per cent., indicating reduced color index; whites, 6,470, differential count of 200 (eosin and methylene blue). Small mononuclears 10.5 per cent.; large mononuclears and basophiles, 28.5 per cent.; neutrophiles, 54 per cent.; eosinophiles, 8 per cent. No malarial organisms; some leucocytes pigmented.

Blood count five days later showed 3,981,000 reds; hemoglobin, 80 per cent.; whites, 10,180, 70 per cent. of which were neutrophiles; eosinophiles and small lymphocytes gaining. Discharged on June 20 feeling quite well.

The following is a case of typhoid fever with irregular temperature curve:

CASE 8.—W. J. R., aged 21, male, white, clerk. After a two-day malaise he went to bed on July 20, 1901, with a chill, followed by high fever and going off in a sweat. The first temperature reading, taken at this stage, was 104 F. Blood examinations on fever chart; malarial count, leucocytosis, no plasmodia. Next day he had another chill, followed by rise of temperature to 105.2; no plasmodia; no local symptoms to account for chills, pus suspected; bowels constipated and paretic; enema and salines given. Fever then assumed a remittent type and leucocytes diminished; relative increase in small lymphocytes. Widal reaction positive on first and only trial, on sixth day. The case now ran typically typhoid until in the third week there was another chill with leucocytosis; no plasmodia; no quinin given. From now on fever gradually subsided and he made an uneventful recovery. A year later he developed a suppurative appendicitis and was successfully operated on. I am now quite sure that this is what complicated his typhoid fever. I should add that no adhesions were found at the operation. The accompanying temperature chart completes the history.

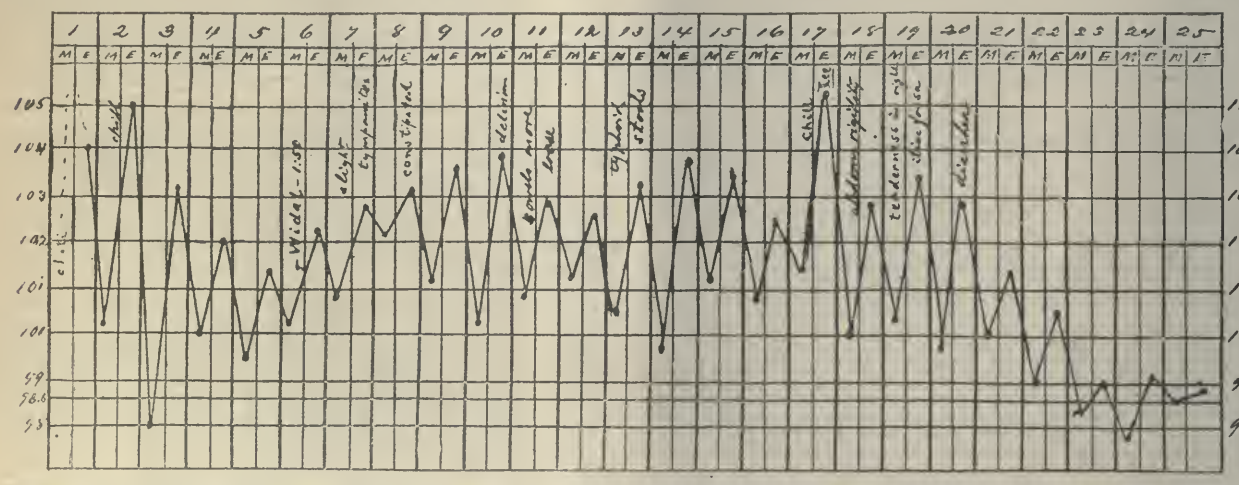

Chart 3, Case 8.—W. J. R. Typhoid fever, with chills. Blood, first day: No plasmodia; no pigmented leukocytes; white cells, 12,020, stained eosin and m. blue; small lymphos., 22, or 11 per cent.; large lymphos. and basophiles, 46, or 23 per cent.; polys., 130, or 65 per cent.; eosinophiles, 2, or 1 per cent. Sixth day: No plasmodia; Widal in 1:50=30 min.; small lymphos., 18 per cent.; large lymphos., 15 per cent.; polys., 67 per cent.; eosinophiles, 0 per cent.; total leukocytes, 9,340. Seventeenth day: No plasmodia; white cells, 16,310; 77 per cent. polys. This case presents a leukocyte proportion resembling that of malaria, except as to polymorphonuclear cells.

Without a blood examination this would have been regarded as a case of malarial fever with intercurrent typhoid.

Now, in conclusion, a few words as to our methods of diagnosis. The Widal reaction is open to fallacies. Even if the culture is just right and the drop contains no fibrin, we have errors estimated at from 3 to 12 per cent. either way. Frequently a single test is all that can be made and the reaction, if transient, may escape us. We also know that it may persist from a former attack and which was perhaps not recognized.

On the other hand, to what do we refer the Widal test as standard? When can we say that it has failed? The blood culture test only appears in about 70 per cent. or less of apparent typhoids. If we have a patient with no symptom but fever, but whose blood gives a Widal reaction, we say he has typhoid fever, yet we have such cases that do not react to typhoid culture and are undoubtedly cases of thermic fever. Yet when we have a case with typhoid symptoms and no Widal we say that the test has failed. In the first instance we reject the negative clinical evidence and in the second we reject the negative laboratory evidence; we do not question the reliability of the Widal test in the one, but we do in the other.

As regards malarial infection, we are by no means a unit as to the diagnostic value of a few infected red corpuscles. We certainly do have latent "malaria," though, perhaps, never without symptoms, and any intercurrent disease may drive the parasites into the peripheral circulation; we attribute the fever to the parasites and cinchonize, sometimes with effect on the fever, sometimes without. The result is conflicting opinion as to the value of quinin in malarial fevers. The so-called malarial leucocyte count is not always characteristic; I have found it repeatedly in fevers giving the Widal reaction when there were no plasmodia. If we make a spread by drawing one slide lengthwise of another and count only within the leucocyte fringe we find relatively less small lymphocytes, because these are left behind with the red cells.

SUMMARY.

We might summarize our paper, then, as follows:

1. A very sudden hyperpyrexia in midsummer is more apt to be sunstroke than "congestion." Do not give quinin without cause.

2. The malarial leucocyte count is only collateral evidence of malarial infection, and the count must include all the cells in the spread.

3. The Widal test may lead us into error in a small percentage of cases; the blood culture test is more difficult and has no negative value.

4. A chill or fulminant onset of a typhoid fever is not sufficient evidence of a complicating malaria.

5. A chill or sudden disturbance of the temperature curve during convalescence in typhoid fever is not necessarily malarial.

6. In a malarial infection the persistence of an irregular subcontinuous fever after thorough cinchonization is not evidence of a typhoid complication or of remaining plasmodia.

7. A positive diagnosis of summer-fall fevers is not always possible.

8. In the hygienic management of summer-fall fevers we should presuppose a double infection, irrespective of symptoms.

9. Some of the summer-fall fevers are typhoid, some are malarial and a few of them are neither one, but the writer is opposed to the belief in an X fever.

The Great Charite Hospital at Berlin.—Besides the 147 physicians connected with this hospital there are 603 other officials or attendants. There are 1493 beds and 68 infant cribs. The number of patients treated last year was 19,121; the average stay in the hospitals 28.8 days; the expense per day and capita 3.36 marks or about $0.84. The house staff numbers 519. The *Allg. Med. Ct. Ztg.* for April 26 gives other details of the establishment which consumed last year nearly half a million eggs, 44,478 liters milk, 30,602 herrings and 36,856 kilograms butter, etc.

A CLINICAL OBSERVATION OF NINETY CASES OF TYPHOID FEVER.

WITH FOUR DEATHS, WITH SPECIAL REFERENCE TO THERAPEUTIC FASTING.*

R. M. HARBIN, M.D.
ROME, GA.

While a statistical study of typhoid fever is not in strict accordance with the caption of this article, there is a valuable amount of information as to the etiology of the disease furnished by the vital statistics of the Twelfth Census Reports and, for a practical observation, a few facts may be referred to without impropriety.

The geographical distribution of typhoid fever shows a greater prevalence in the southern states, including the Carolinas, Georgia, Alabama, Mississippi and Tennessee, the death rate being 76.1 per 1,000 deaths. Next highest mortality is 69.5 for Louisiana, Missouri, Arkansas, Indian Territory and Texas. Of the latter 80.6 is rural and 38.7 is cities. The general rate for rural is 48 and cities 19, which suggests a greater source of infection in the rural districts. Nearly every source of the infection can be excluded except the drinking water, which is contaminated by the soil. My own observation of the cases herein reported warrants that belief, as 79 cases drank well water and 11 cases drank hydrant water, and the greater proportion of the population in the

locality where this observation was made is dependent on hydrant water for drinking purposes.

It will be observed in Table 1 that the general death rate per 1,000 deaths from typhoid fever is 34. In Georgia the rate is 58, while New York has 13 and Massachusetts has a rate of 12. Atlanta, Ga., has a rate of 40, while New York City has 8.

As will be observed, the death rate in Georgia is less for the colored race, being 46, while that of the white is 71. The disease is evidently less frequent and less fatal in the colored race. This disease, excepting tuberculosis and pneumonia, claims more victims than any other disease in the south and, excluding the infant mortality of pneumonia, it is second in causing more deaths in adult life. According to death rates given by the census report in the rural districts of Georgia, there were 1,325 deaths from typhoid fever, while tuberculosis claimed 1,668.

A greater number of deaths from typhoid fever occur in the months of August, September and October and there is a more frequent occurrence after a season of heavy rainfall. It is pre-eminently a disease of early

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

adult life, and the average age at death of all cases in the United States is 28.8 years. Typhoid fever shows a marked predilection for occupations. As will be observed in Table 2, farmers have the highest death rate, 58 per 1,000 deaths, excepting teachers, which is 98. Nurses have a rate of 56, miners 43, clergymen 37, and physicians and lawyers 23. It will be observed that physicians, although in contact with the disease, do not often become infected and nurses are not more often infected than other classes. There are more people ill with typhoid fever during the year than any other disease, especially farmers. Estimating the mortality of typhoid at 15 per cent., tuberculosis 75 per cent. and pneumonia 20 per cent., there were farmers ill from typhoid fever 37,710, from tuberculosis 14,735, and from pneumonia 55,003. The same observation is noted for other occupations.

The death rate per 100,000 population for various occupations is as follows: Farmers, 32; miners, 38; physicians, 33; clergymen, 46; lawyers, 31, and nurses, 47.

These facts may be summarized as follows:

The death rate from typhoid fever in the south is startling and claims about an equal number of deaths among the whites as tuberculosis, and well water is probably the source of infection.

There are more adults ill from typhoid fever during the year than any other disease in Georgia.

Table 2.

	Deaths, All Causes.	Typhoid Deaths, per 1000 Deaths.	Tuberculosis Deaths, per 1000 Deaths.	Pneumonia Deaths, per 1000 Deaths.	Typhoid Cases, 15 per cent.	Tuberculosis Cases, 75 per ct. Farmers. .	96,502	58	106	114	37,710	14,735	55,003	32	147	140
Miners. . . .	5,895	43	97	127	1,709	820	30,000	38	120	77
Physicians	2,322	23	93	87	347	306	1,011	33	168	178
Clergymen	2,062	37	98	95	503	291	980	46	123	255
Lawyers .	1,508	23	107	72	233	213	541	31	139	132
Teachers .	1,256	98	208	95	820	381	600	. . .	182	144
Nurses . .	582	56	103	91	220	90	212	47	100	93

Farmers, next to teachers, have the highest death rate.

The average age at death is 28.8 years.

Most writers agree that typhoid fever is a water borne disease. The *New York Medical Record,* in an editorial, says: "While agreeing with a majority of investigators, we believe that water is the chief agent in the causation and dissemination of typhoid fever, and we admit that it may be air borne, being transmited by dust, flies," etc. Dr. Leigh Canney in a recent book regards the question of etiology as a question of pure or impure drinking water. Flies among the poor furnish a means of conveyance of infection, as the writer has often observed cases imported in families in small houses, and the disease spreads to other members of the family.

In this report of cases only clinical diagnoses were made and the suggestion of Professor Osler was adopted, viz., any fever continuing beyond ten days and resisting the influence of quinin may be assumed to be typhoid.

I regret not having a Widal test of these cases to report, but, after all, the clinical diagnoses may be quite as reliable, as only 70 per cent. give a Widal reaction before the end of the first week, according to the New York health department. All the discussions and controversies prove that no routine drug treatment of typhoid fever has any specific value. Of course symptoms should be controlled by appropriate remedies.

Turpentine was the only routine drug used in these cases, and it certainly relieves the intestinal symptoms better than any remedy at our disposal. It has been used longer and more widely than any other remedy, and its popularity still maintains with clinical observers of long experience.

Dr. Baird, at a meeting of the Georgia Medical Association, 1902, gave a résumé of the treatment of typhoid fever by 24 authorities and may be summarized in a few words: rest, diet, cold bath, etc. My own experience convinces me that the above summary represents the facts of the question, and it behooves us to study more closely the details of the rest, diet and bath treatment and our results would give us a greater percentage of recoveries.

As seems to the writer the dietetic treatment is the most important of all and no drug can counterbalance the baneful effect of dietetic sins. Fasting as a therapeutic measure has proved so valuable to me in the treatment of these cases that I account for the low rate of mortality by no other part of the treatment. The pathologic anatomy of typhoid fever shows a condition of gastrointestinal catarrh with hyperplasia, with a great reduction of all the digestive fluids. Saliva is diminished and hydrochloric acid is usually absent in the gastric juice and, in fact, almost every condition unfavorable to digestion exists. Diarrhea is an effort of Nature to throw off what the intestines can not digest. Intestinal ulcers should be assumed to exist in every case, however mild, and the proper treatment of ulcers is rest.

The rational treatment of such a condition is a restricted diet or fasting, then peristalsis can be better controlled by cold application and an opiate may be used if much diarrhea exists.

The eliminative treatment, so called, is irrational and would be unnecessary if there was no surplus of food in the intestines to dispose of.

The active symptoms in the first stage of the disease can be better controlled by fasting for 24 to 48 hours or even longer, than by any other remedy and the effect of any other remedies applied will be greatly enhanced. The effect of the cold bath is much more marked. I have often noticed that the temperature can be reduced 2.5 degrees by a simple sponge bath. Many patients exhibit marked peculiarities as to the effects of cold applications, most cases having an agreeable effect during a high temperature, while in others having an exciting effect. The Brand system being more or less impracticable, recourse is had to the modified cold bath or even a hot bath. Each case should be studied on its own merits and the cold, warm or hot sponging applied accordingly. In fact, some observers have claimed better results from the hot bath. The patient's comfort should not be lost sight of in the bath treatment. It has been my observation that cold is better for some, while warm sponging is better for others, and still in other cases cold and hot sponging alternating has been better. In sthenic cases, with very high temperature causing delirium, ice-cold applications are preferable and in later stages, where the temperature is not excessive but delirium exists, warm sponging has a more soothing effect. In asthenic cases, with hyperpyrexia, the cold and warm alternating seem to act better. Rubbing enhances the effect of these applications and heat is thereby dissipated. It has been stated that 30 per cent. of the entire quantity of blood in circulation remains in the cutaneous system and the intimate relations between the physiologic function of the skin and temperature variations of the body both throw light on the

importance of sponging in typhoid fever. An excess of food in the intestines increases peristalsis and favors the absorption of toxins. The writer has observed an increase of several degrees of temperature in a quiescent case by taking a dose of castor oil.

It is a clinical fact that emaciation is less from typhoid fever than any other acute disease, and the danger from inanition is slight. A recent writer[1] observes "that emaciation seemed to be independent of the amount of food taken into the stomach," and the same observation has often been made by myself, which would show that nutrition is not dependent on the amount of food taken into the stomach. Many cases run an

1. Lewis Med. Rec., vol lxii, No. 5.

abortive course after the amphibolic stage under a treatment of fasting and a restricted diet. After fasting 24 to 48 hours a very restricted diet should be given, consisting of broths of beef, chicken, mutton, oysters, etc., coffee, cocoa, egg albumin, peptonoids, etc., in prescribed amounts.

Gelatin is a valuable adjuvant in the dietary of a typhoid patient. It serves three purposes: adds to the relish of the various liquids, lessens the nitrogenous waste from the system and prevents hemorrhage. A teaspoonful three or four times a day is the amount usually ordered and should be dissolved in a little hot water and then added to any liquid nourishment, meat broths, cocoa, coffee, tea, etc. It adds a richness of taste to these slops, which otherwise become tiresome to the patient. The food value of gelatin is recognized and, being in a concentrated form, serves an excellent purpose. When used, emaciation is less rapid. The hemostatic effect of gelatin is universally conceded, but to wait until an intestinal hemorrhage has occurred but little immediate good can be hoped for by its use. It should be used as a routine in all cases to prevent hemorrhage. Very aggravated diarrheic cases do not tolerate it so well, as it may increase tympany. But in these cases it may be used on alternate days in small quantities. Since beginning its use no hemorrhage has occurred. The case should be closely studied, and any excess of food will be indicated by a rise of temperature. To nourish the patient by a minimum amount of food requires a very close study. Milk should be absolutely forbidden, because no one can predict when it will form a curd, which is worse than any solid food. One of my patients had a hemorrhage in convalescence from taking milk and lime water, equal parts. I examined curds the size of a hazelnut in the bloody dejecta. The case was a mild one. It is valuable, however, diluted with two to five parts of coffee, cocoa, broths, hot water, as under these circumstances the danger of curd formation is light.

This plan of dietetic treatment should be continued until active symptoms are controlled and, as improvement advances, nourishment may be more liberally given. Solid food is a danger that offers few advantages to the patient. Nearly all recrudescences are due to dietetic errors. Fasting in late stages and convalescent stages will cause fever, as inanition often causes fever.

Below is a summary of the table of reported cases: Of the cases 87 were white and 3 colored. The youngest was 2, and occurred with 4 others in the same family, and the oldest was 60. Cases under 10 were 20; between 10 and 20, 29 cases; between 20 and 30, 20 cases; over 30, 21 cases. The average age was 19.4. There were 48 males and 42 females. As to the months of occurrence, August claimed 27; September, 21; July, 16; October, 15; November, 5; June, 4, and April, 2. Those classed mild were 58 and those severe 32. Gastro-intestinal symptoms were marked in 36 and absent in 54. Nervous symptoms were marked in 18 and absent in 72. The average duration was 19 days, and the same without relapes was 17 days. Five, or 5 5/10 per cent., of the cases relapsed, and all recovered. The relapses were ascribed to taking too early of solid food. Five cases were complicated. Three, or 3.3 per cent., had hemorrhage, two of which were slight and the third immediately fatal from getting up in delirium.

One case (No. 88) was diagnosed appendicitis and on the fourth day an apparently normal appendix was removed and the case pursued a typical course of the disease to recovery.

Case 72 had hematuria and recovered.

Case 24 had double parotid suppuration and osteitis of the humeri, and after forty-five days recovered.

Case 14 had an attack two months previous.

Of the four deaths (4.4 per cent.) Case 46, a negro, can, with propriety, be ruled out, as he was dismissed and I was called to see him in a relapse, in a dying condition, having had urinary retention twenty-four hours.

Case 57 would probably have recovered, but, being without a nurse, she got up in delirium and a fatal hemorrhage resulted.

Case 70 contracted pneumonia on the tenth day of convalescence and died a week later. It was the opinion of my colleague that there was no reinfection of typhoid fever.

Case 64, a negro, alcoholic, died on the twelfth day from asthenia.

Of 87 whites treated there occurred 2 deaths, or 2.2 per cent.

The conclusions to be adduced are as follows:

1. Fasting and a restricted diet are indicated because of pathologic conditions.

2. A clinical fact maintains that emaciation occurs independently of the amount of food taken.

3. All severe cases should be subjected to fasting for 24 to 48 hours to relieve the active symptoms, which exhaust the patient more rapidly than the lack of food.

4. After a fast should be prescribed a restricted diet of broths, diluted milk, etc., in definite quantities.

5. Gelatin prevents too rapid emaciation in certain cases and renders hemorrhage less liable.

6. The cold bath or the modified cold bath is more effective during a fast.

7. Peristalsis favors the absorption of toxins and cathartics should be used only to remove undigested food.

8. The presence of intestinal ulcers should be assumed to exist in every case and the proper treatment is rest, which is better attained by fasting and a restricted diet, thus preventing hemorrhage and perforation.

9. The presence of diarrhea and vomiting indicates the adoption of the fasting treatment.

10. Fasting and a restricted diet shorten the course of the disease and many cases run an abortive course after the amphibolic period.

11. Many of the vaunted cures from specific drugs are dietetic in fact.

12. Recrudescences are nearly always due to dietetic errors.

13. In the above report, 45 consecutive cases occurred without death. Of 87 whites, 2, or 2.2 per cent., died. Of colored, 2 died, and the low mortality of 4.4 per cent. of all cases was ascribed to the above treatment.

TYPHOID FEVER IN COLORADO.

A REPORT OF FIVE HUNDRED AND TWENTY-NINE CASES.*

J. N. HALL, M.D., AND C. E. COOPER, M.D.
DENVER.

We report to-day our conclusions regarding a series of cases of typhoid fever at an altitude of about 5,000 feet, in order to compare the disease as we see it with typhoid fever in general.

There occurred 225 cases in the private practice of Dr. Hall in Colorado, 54 of these being seen in consultation;

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

292 cases, most thoroughly recorded and analyzed by Dr. Claude E. Cooper, Denver, late house physician at the Arapahoe County Hospital, occurred in the wards of that institution between 1896 and 1902. We include only 12 of the cases seen by Dr. Hall in his service at St. Anthony's Hospital, the records of cases at this institution for several years being too incomplete for inclusion. He did not personally see all of the cases reported from the Arapahoe County Hospital, and he here tenders his thanks to his colleagues for permission to use the hospital records.

The males and females were almost equally distributed in the private cases, the numbers being 116 and 109 respectively. In the hospital cases males predominated, 241 to 63.

The total deaths were 77, a percentage of 14.5 per cent. The male rate was 14 per cent., the female, 15.6 per cent. That for private practice, 14.2 per cent., is unduly high, owing to the fact that nearly a fourth of them were seen with other physicians, and were naturally grave cases. Of the 171 cases cared for by Dr. Hall in private practice 16 died, or 9.3 per cent. It is well recognized that the mortality in family practice is generally less than in the hospital, owing to many favoring conditions.

The exact cause of death can not be given in every case, since possibly pneumonia, hemorrhage and heart disease occur in the same patient. As nearly as they can be stated, however, the causes were as follows: Intestinal hemorrhage, 15; general hemorrhage, 3; hemorrhage from face (noma), 1; abortion and uterine hemorrhage, 1; perforation without hemorrhage, 7; perforation with hemorrhage, 7; pneumonia, 14; convulsions, 2; edema of larynx, 1; nephritis, 1; organic heart disease, 2; accidental poisoning by irregular practitioner, 1; heart failure (in three cases after the subsidence of the fever), 7; general toxemia and exhaustion, 15.

Arranged by age, the distribution of the cases is as follows:

8 months of age	1	31 to 40 years	108
2 years of age	1	41 to 50 years	25
3 years of age	5	51 to 60 years	8
4 years of age	2	61 to 70 years	3
5 years of age	9	Age not given	5
6 to 10 years	20		
11 to 20 years	128	Total	529
21 to 30 years	214		

The great preponderance of cases in adolescents and young adults is very noticeable, over 85 per cent. occurring between 11 and 40 years of age. The deaths were distributed as follows:

Under 5 years	0 or 0 per cent.
Between 6 and 10	2 or 10 per cent.
Between 11 and 20	15 or 11.7 per cent.
Between 21 and 30	28 or 13 per cent.
Between 31 and 40	18 or 16.6 per cent.
Between 41 and 50	10 or 40 per cent.
Between 51 and 60	1 or 12.5 per cent.
Between 61 and 70	1 or 33.3 per cent.

In two fatal cases the age is not given. Thirteen of the cases had had a previous attack of the disease, and two have had subsequent attacks, one being reported to us as fatal twenty months after the attack recorded here.

Relapse occurred in twenty-three cases, according to the records. We are practically sure that this percentage, 4.3, is rather too low, for the charts are not all complete. But three of these were fatal, one patient recovering after two relapses, and a total febrile course of four months.

As to symptoms present the records are not complete, and only positive or negative statements are here given.

Rose spots are noted in 270 cases.

Enlarged spleen in 155 cases.

Distended abdomen in 168 cases.

Diarrhea in 119 cases.

Constipation in 77 cases.

Unusually high temperature in 34 cases.

Medium temperature in 196 cases.

Moderate temperature in 103 cases.

Three cases are noted as having temperature over 106, and all died.

Many of these cases were seen before the introduction of the Widal test. It is recorded as positive in fifty instances, but negative findings are not noted. No cases of paratyphoid fever were recognized.

Delirium worthy of record is noted in fifty-eight cases, of which twenty-two died. It does not appear to be an especially dangerous symptom. Distinct chills are noted in fifty-three cases, and chilly feelings in thirty-one. In four of those in whom repeated chills occurred during the course of the disease phlebitis was noted, while two cases with severe paroxysms had none. In one woman the chills were erroneously thought to be septic at first, owing to a recent miscarriage. Phlebitis is noted in twenty cases, but in some of the hospital cases the records are certainly at fault, for Dr. Hall has had as many as five cases on hand at one time in the county hospital. We think this number should certainly be doubled. It is apparently more frequent in the cases that are treated by tubbing. Phlebitis is certainly much more common here than the statistics commonly given would lead one to expect. In January, 1899, Dr. Hall had a patient in St. Luke's Hospital with this complication, and every patient admitted during the previous fall had suffered similarly, probably eight or ten cases in all. But three patients with this complication died. Two cases with double phlebitis recovered. In one case the trouble extended to the veins of the left hip and loin.

Lobar pneumonia occurred in twenty-three cases, fourteen of these dying. No exact record was kept of other pulmonary complications. Hemoptysis occurred in five cases, one of these only being tuberculous. In one case lobar pneumonia was present, in one abscess of lung, while in two the bleeding was unexplained. Two of the cases died, the one with pneumonia and one uncomplicated case.

A distribution of rose spots so general as to resemble the eruption of measles was noted in four cases, while in many others they extended to the limbs, though not to the face.

Pregnancy complicated seven cases, while two developed during the lying-in period. One woman was delivered of a healthy child while the temperature was 104, but recovered without complications. One at the beginning of the seventh month of the pregnancy had a severe attack, with three hemorrhages and relapse, but bore a living child at full term. One in the eighth month died of chronic parenchymatous nephritis, the immediate cause being laryngeal edema. She had two hemorrhages from the bowel, and the Widal test was positive. One died of intestinal hemorrhage in the fifth month. Two cases in the fifth month passed safely through the disease, and one aborted early in the pregnancy and died. Of the two cases developing in childbed one recovered.

In eleven cases such nervous manifestations occurred as frequently give rise to the diagnosis of meningitis, and curiously ten of them recovered. In one case Dr. Hall coincided with Dr. C. G. Hickey in a probable diagnosis of tuberculous meningitis, but the woman developed a severe attack of typhoid fever and recovered. One woman screamed for many days with headache when not under the influence of morphin or other drugs, but after many tub baths made a perfect recovery.

Great interest centers about the heart in this fever. Five cases were complicated with valvular disease. A boy of 13, as he recovered from scarlet fever, came down with typhoid. He died of complicating pneumonia at about the fifteenth day. He presented the systolic thrill and harsh murmur, with cyanosis and dyspnea, of congenital pulmonic stenosis. A girl of 5 years with mitral regurgitation following rheumatism passed safely through the disease, as did a girl of 15 with aortic and mitral leakage of very moderate degree following chorea. A girl of 17, not treated by Dr. Hall, but seen once by him in an emergency and not included in these figures, died in the height of the fever of well-marked aortic regurgitation, being mentioned merely to show the danger of prolonged fever even when compensation has been perfect. A man of 23 with well-marked aortic incompetence recovered. One woman with serious mitral disease recovered from the fever, but died of cardiac failure a few weeks later. One woman of 37 with a very mild attack died of sheer cardiac weakness on the seventeenth day, with absolutely no complications. Neither Dr. Hickey nor Dr. Hall could find any possible cause for such an unusual death, excepting a previous starvation diet. The woman had gone mad over some of the pernicious literature recommending a diet of fruits, and had literally lived on such a diet for months before her death. When doing obstetric work Dr. Hall frequently saw women so weak as to require the forceps from this cause, but did not realize the danger of the writings mentioned as regards typhoid fever.

One man and two women died of cardiac weakness after the fever had long disappeared, and a woman of 67 had serious general edema from cardiac failure during her convalescence, but recovered on being sent to her home in a lower altitude. A feeble girl of 8 years died of hemorrhage from a facial artery due to noma.

Two cases with purulent otitis media recovered. One patient with pleurisy with effusion recovered without tapping, and one died, but we have no record of the exact cause. Gangrene of the right leg from popliteal obstruction necessitated amputation in an epileptic of 36 years. Suppuration of the hip joint occurred in a boy of 15, proving fatal, and a man of 22 with suppuration of the left elbow recovered. The epileptic male just mentioned, another male of 20, and a female of 23 recovered from attacks of confusional insanity following the fever. Since these statistics were gathered a girl of 22 in the insane wards of the county hospital recovered from the mania for which she had been committed months before, as she convalesced from an attack of typhoid.

One male of 28 had acute nephritis of great severity after his relapse, but recovered. The woman already mentioned as being pregnant, and an alcoholic man of 36 died with chronic parenchymatous nephritis during the disease. Many patients presented albumin, but we have no accurate record of its occurrence.

Fourteen fatal cases of perforation have been mentioned. One of these, a boy of 17 who entered the hospital twenty-four hours after the accident, was promptly operated on by Dr. Leonard Freeman, but died, as we had reasons to expect he would do. An autopsy proved that a single ulcer existed but a few inches from the cecum. It would have been an ideal case for operation if only seen earlier. A male of 29 years also died after operation, while a man of 23 recovered after operation by Dr. S. D. Van Meter. He died of fecal obstruction less than a year later, from a band of adhesions about the former wound. A man of 26 whom Dr. Hall saw with Dr. T. E. Taylor, recovered from a typhoid perforation, an ischiorectal abscess opening just to the right of the anus, as a result of the walled-in infection. This had not closed nine months later. After careful consideration we feel sure that this was typhoidal, and not appendiceal, although no Widal test was made.

False symptoms of perforation are noted five times. A boy of 17 had screaming pain in the right flank, rigidity and rise of temperature, but no further symptoms and recovered promptly. A man of 25 had similar pain, partial disappearance of liver dulness, a leucocytosis of 13,000, and then a subsidence of all symptoms. A man of 37 had similar symptoms in his second relapse, and recovered, and at autopsy in a similar case a local peritonitis without perforation was found. In a woman of 30, at postmortem examination, we found some blood in the bowel, though no external hemorrhage had occurred, and bubbles of gas under the peritoneal coat of the small intestine, but no actual perforation. She had presented symptoms pointing toward this accident before death, but had no leucocytosis.

The occurrence of petechial eruption in typhoid is rightly regarded as rare, and as usually of fatal import. In five of these cases this phenomenon was seen, three of them dying. A male of 26 had hemorrhages from the mucous membranes as well, and died. A boy of 16, comatose from the start, had petechiæ limited to the chest, dying in the second week. A mulatto male of 21 with many subcutaneous hemorrhages had widely dilated heart and loud mitral murmur. Dr. Hall suspected malignant endocarditis from the sudden cardiac developments, but autopsy showed only severe and typical typhoid lesions. A male of 26 with many hemorrhages under the skin and edema of the feet, and a male of 39, with a moderate fever and petechiæ, recovered. This rare complication is obviously not to be regarded as necessarily fatal.

Five patients are noted as suffering from chronic pulmonary tuberculosis. A male of 28 died with a pleural effusion, as already mentioned. A female of 42 recovered, as did three males of 19, 28, and 27 years respectively, the latter having a pulmonary hemorrhage during the fever.

Two males aged 20 and 42 years respectively passed segments of beef tapeworm, and both recovered. In a male of 33, who recovered, the plasmodium malariæ was found. He had active chills superadded to his febrile temperature.

Several suppurative conditions are of interest. General furunculosis during recovery is noted but once, but it must have occurred oftener. Abscess of the right parotid gland, opening through the ear and afterward opened externally, occurred in a man who recovered. Noma proved fatal in a feeble girl of 8. An abscess in the left groin from bedsore resulted fatally. Two abscesses of the axilla, one of the breast, one of the neck, and one in the erector spinæ muscles near an old bullet wound, are noted, all the patients recovering. The patient who had acute nephritis had abscesses in the bursæ about the left elbow and right wrist, and one in the buttock, but recovered. The typhoid bacillus was not found, but the cocci of suppuration were abundant.

Peripheral neuritis is recorded in three cases, all recovering; once in the left arm, once in the legs and feet, and once limited to the parts supplied by the ulnar nerves. But three cases of the peculiar neuritis described as "tender toes" are noted, but we recall more than that in the county hospital. They were exclusively in patients who were tubbed, all recovering.

We shall mention briefly some of the rarer complications and curiosities of the series. One woman had a wandering left kidney, with severe Dietl's crises. She became pregnant in convalescence, and no further symptoms from the kidney came to notice. One woman with distinct appendicitis developed typhoid during convalescence. In one woman a large external pile sloughed off. One young man died while vomiting. One woman of 41 died with intestinal obstruction during a well-marked attack of typhoid. Impaction of feces in the rectum required manual removal in one woman. Erysipelas complicated one fatal case. In a boy of 16 who recovered the spleen reached to the median line, but the cause, almost certainly not typhoid, is not specified. In a boy of 10 years jaundice with some enlargement of the liver took place, presumably of the catarrhal variety. He recovered. Pericarditis with fatal result occurred in a woman of 34. Gonorrhea in a male patient pursued its normal course. One patient with serious hiccough recovered. In two instances six cases of the fever occurred in one family. One patient, after a severe attack, had acute lobar pneumonia, affecting in succession three separate lobes, and recovered after months of illness. Marked muscular rigidity was noted in one of the fatal cases with petechiæ. We regard it as an ominous symptom. A female of 18 died in convulsions on the ninth day, and a male of 31 years. In neither was kidney disease recognized.

The treatment in general was symptomatic, the temperature being generally controlled by bathing. It was interesting to compare the death rate among those tubbed with that of those treated by sponging and by electric fan baths.

One hundred and twenty-four were treated by tubbing at a temperature of 70, or as near that as could be used whenever the two-hourly temperature rose to 102.5. Alcohol was given just previous if the heart was weakening perceptibly. This treatment was used in the severer cases generally, and was applied almost exclusively in the county hospital patients. Yet but eighteen of these patients died, a percentage of 14.5, which is exactly the average for all the cases. We regard this as a great triumph for the method, for the average death rate of all county hospital cases was 15.1 per cent., including many of the milder cases not tubbed.

The causes of death of the eighteen patients submitted to tubbing were: In three cases pneumonia alone. In eight cases, intestinal hemorrhage. One of these was convalescent from diphtheria, and had a systolic apical murmur; local peritonitis and pneumonia occurred in one case. Pyelitis complicated another case, and perforation another. Abortion in one case. Convulsions in one case. Perforation in one case. General hemorrhage in two cases. Long-continued pyrexia in one case. Nervous complications and relapse in one case. It is obvious that hemorrhagic complications are less under control by tubbing than other causes of death, and probably perforation as well.

About 350 cases are recorded to have been sponged, but as practically all not tubbed were sponged to a greater or less extent, and as a fan bath was used in a few, we shall not attempt to analyze these cases further.

We may conclude from this analysis of a considerable number of cases covering twenty years in different parts of Colorado that typhoid fever is practically the same disease here as elsewhere. Many cases called mountain fever by some have been included in this series, for we know of no such disease. Typical examples have had hemorrhages, rose spots, Widal reaction and many of the complications of typhoid, and are certainly typhoid. The false name is passing out of use here.

Dr. Hall concluded in 1889, from an analysis of his first 108 cases, that typhoid fever was milder here than in the East. A wider experience convinces him that it does not differ materially in this nor in any other respect from the disease as reported from this and most other countries. He believes that diarrhea is somewhat less frequent with us in Colorado.

We shall certainly continue for the present tubbing in severe cases, the avoidance of medicinal antipyretics, the use of alcoholic stimulants when called for by rapid and feeble pulse, and the recommendation of operation in cases of perforation seen early. We are not yet convinced of the advisability of feeding solid food before the fifth or seventh day after the temperature reaches normal, excepting in cases with exceptionally mild attacks and with clean tongue.

DISCUSSION

ON PAPERS OF DRS. HAPPEL, KRAUSS, HARBIN AND HALL.

DR. T. B. FUTCHER, Baltimore—I am not convinced that the cases referred to were not a mild form of typhoid fever. We all know that typhoid fever may present a great variety of clinical pictures; we all know that typhoid fever does not, in all instances, present enlarged spleen, epistaxis, rose spots, etc. There was one point in particular that impressed me, and that was the absence of a frequent examination of the blood serum for the Widal reaction. I believe that before we exclude the possibility of typhoid fever in these cases it is very important that the blood serum should be examined repeatedly for the Widal test. This is the routine at the Johns Hopkins Hospital, an examination of the blood serum in practically all cases of typhoid fever being enforced, especially when the patients leave the hospital, and a certain proportion of the cases show this reaction on the day of discharge.

There is another point that should be kept in mind that possibly they may have a paratyphoid infection. It is well known that in a large number of the typhoid cases among soldiers of the South African war, a number of them did not give the positive reaction after the Widal test, but were considered to be cases of paratyphoid infection.

The occurrence of chills and sweating in this series of cases is of interest. With reference to the coal-tar products it should be kept in mind that they will produce chills and sweating of a fairly severe grade. Chills and sweating may occur at the onset of the disease, at the onset of complications, or at convalescence; it should also be borne in mind that the coal-tar products will produce the same. Until more convincing bacteriologic and pathologic evidence can be brought forward to exclude the possibility of typhoid fever being the cause of these symptoms I think we must be rather conservative in stating that these cases are not cases of mild typhoid fever.

DR. JAMES TYSON, Philadelphia—While it is far from my wish to make a diagnosis in cases of continued fevers in Mississippi, I feel that in 30 years' experience in the study of fevers the tendency has been to limit the number of continued fevers. Each winter it happens to me to have one or more cases of anomalous fever which elude a diagnosis for a longer or shorter time, and invariably at the end of a certain period the cases will turn out to be typhoid fever, or malarial fever, or some of the more unusual modifications of typhoid fever, such as paratyphoid or colon-typhoid. On the other hand, there can be no doubt that fever may be kept up by irritating causes in the intestines, such as indigestible articles of food, or ptomains.

I was much interested in what Dr. Hall said regarding typhoid fever during pregnancy. In the wards of the University Hospital it has happened to me during the past winter to have had three cases of typhoid fever occurring in pregnant women, and their terminations were quite different from those we are led to expect from text-book descriptions of typhoid

fever in the pregnant woman. One was a woman eight months pregnant, and she was delivered successfully of a living child and recovered. The remaining two were pregnant five months, and both passed through an ordinary mild attack of typhoid fever and recovered.

DR. J. A. WITHERSPOON, Nashville, Tenn.—This question I have been studying for ten or twelve years. To say that this fever might be paratyphoid fever is begging the question. If it is paratyphoid fever it, then, is not typhoid fever. The germ of paratyphoid fever is very different from the germ of typhoid fever. However, there is a fever in the southern states which, clinically, is different from malaria or pure typhoid fever. I will detail a few of these differences. Several years ago I suggested for this type of fever "toxenteric fever." Why? Because I did not know the cause of this peculiar kind of fever. I do know, though, that it was due to some infection, possibly in the bowel, but whether it was due to some heterogeneous germs, or specific germs, I do not know. It starts out, as described in Dr. Happel's paper, but suddenly, not gradually; it does not specially occur in the season of the year that typhoid fever does; it occurs in all seasons; it does not occur at any particular age, but may occur anywhere from the cradle to the grave; one attack does not protect against further attacks, but makes one more liable. I have seen five different attacks occur in one individual. The bowels are rather regular and the prostation is early, sweating marked, with an irregular type of fever. I have seen a temperature at 9 a. m. of 105 F., and possibly by 10 or 11 o'clock, without the use of any coal-tar products, I have seen the temperature drop to 101 F. In two or three hours there might appear a sudden rise of temperature, then it comes down again, resembling a septic type of fever. I have yet to recognize the rose-colored spots on these patients which is present in most cases of typhoid fever.

The abdomen is not tympanitic, but is rather flat or scaphoid. These patients are constipated with possibly very hard masses, but there is no diarrhea such as we expect in typhoid fever. The tongue is not like that of typhoid, and is not tremulous. There is a lack of hebetude or other nervous phenomena, but rather there is present an irritableness; they exact something, and are rather hungry. Epistaxis is rare. There is a development of herpes labialis in connection with this fever which is rare in typhoid fever. I have yet to see an enlarged spleen. The affection may be paratyphoid fever, but certainly it is not pure typhoid fever.

DR. CHARLES F. MASON, Fort Sam Houston, Texas—I should like to add a few words and add to the testimony of Dr. Futcher, who insisted on repeated examinations for the Widal test if we wish to exclude the diagnosis of typhoid fever in cases of doubtful nature. Where I have been stationed I have seen many cases such as described by the first speaker. It is our custom to examine the blood several times each week both for the Widal reaction and for the plasmodium, with the result that, at some time or other, we have always found one or the other. I wish to emphasize the absolute necessity for repeated examinations. We all know how frequently we find the Widal reaction evanescent.

DR. J. L. CROOK, Jackson, Tenn.—This same question has been freely discussed in our state society. In regard to the diagnosis of these cases, I wish to state that, in my experience, when they have been treated as typhoid fever is treated they practically all recovered. These cases seem to be atypical cases of typhoid fever. With regard to the therapeusis, for five years it has been my plan to institute drainage and antisepsis by the use of calomel and carbonate of guaiacol. In a series of 140 cases the mortality has been less than 3 per cent. When acetozone was used in 9 cases there was no mortality.

DR. R. W. LINDSEY, Little Rock, Ark.—I believe we have a fever in the south that is different from typhoid fever, and from malaria. It is a continued fever, lasting from three to five or six weeks. There are none of the symptoms of typhoid fever, except that it is a continued fever. It is not as grave as typhoid fever. The exacerbations are as liable to occur in the morning as in the evening. Tympany does not occur, and the bowels, as a general thing, are constipated. Until this year, or last fall, I have never had an opportunity of testing microscopically the blood of these cases. Three cases were examined for the malarial plasmodium, and the Widal test made for typhoid fever. These cases lasted three, four and seven weeks respectively. The blood of these cases was examined the first day I saw them, before any quinin was given, and neither the typhoid bacillus nor malarial plasmodium was found. The blood was taken at different stages of the three cases and examined, with like results.

WEAKNESS AND DILATATION OF THE HEART IN CHRONIC NUTRITIONAL DISEASE.*

G. W. McCASKEY, A.M., M.D.
FORT WAYNE, IND.

I wish to invite your attention for a few minutes to some practical questions concerning certain aspects of cardiac pathology and therapeutics. These questions will be discussed with especial reference to my own experience. This experience, or at least that part of it which I have chosen as the basis of this discussion is perhaps sufficiently indicated by the title. It might be well, however, to add that the material among which cases of weakness and dilatation were found comprised about 600 cases of chronic gastritis, with about the same number of other forms of chronic diseases. These cases all occurred in private office and consultation practice. In all cases the heart was subjected to a careful examination with reference to the clinical changes of volume, either transient or permanent in character, which occur with varying states of tonicity of the cardiac muscle.

In perhaps no other department of practical medicine have greater therapeutic advances been made than in that relating to cardiac disease. If Senac could appear before this Association and ask, to-day, instead of the middle of the eighteenth century, his despairing question, "What can medicine do for dilatation of the heart?" he might receive for answer the records of innumerable relative or absolute recoveries. There are few, if any, better landmarks by which to measure the rapid strides of clinical medicine as distinguished from clinical surgery, and demonstrate the lack of consideration and truthfulness of the unfavorable comparisons thus often made.

The great work of Senac was the first important stone in the foundation of modern cardio-pathology and therapeutics, but the structure was very slow in building. Its outlines only began to assume a distinct form half a century later, with the advent of Corvisart, the great physician of the great Napoleon, and later by the labors and discoveries of Laennec, Bouillaud, James Hope and others.

Until a comparitively recent date the recognized pathology of the heart had too exclusive a reference to its orifices, its valves and its membranes. The muscular tissues of the heart to which these appendages are subservient was, in effect, assigned a secondary rôle.

It would be interesting, if time permitted, to epitomize the survey which I have recently made of the manner in which the great writers on the heart during the nineteenth century, which almost exactly corresponds to the evolution of the subject, have dealt with the heart muscle, but time will permit only a few references. Corvisart said that the heart distended the same as does the bladder with urine, but only considered shock, suppression of menses and hemorrhagic flux

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

among the causes of dilatation.[1] He observed the frequency of dilatation of the heart in tailors, tanners, washwomen and others continually bending forward, and attributed it to compression of the aorta. He really devotes considerable space to the discussion of the heart substance, but it is, of course, in the light of a century-old pathology.

James Hope[2] more clearly recognized the ordinary changes in the condition of the heart muscle in dilatation, and treated cardiac dilatation as a primary disease.

Walshe[3] gave very little attention to the heart muscle, but made the important observation that "there are cases in which the heart notably loses its consistence, without there being any permanent blood disease or any obvious affection of the organ itself, except a deficiency in performance."

The work of Stokes,[4] published in 1854, was a great advance on any of its predecessors and really presented a very interesting and, at that time, advanced view of the morbid conditions of the cardiac muscle. He notes that the heart muscle is probaly liable to all the vital and organic changes found in muscle structure elsewhere.

The beginning of the last quarter of the nineteenth century witnessed the publication of Hayden's[5] ponderous volume of 1,200 pages, which, with liberal abstracts and epitomes of the work of his contemporaries and predecessors, fully reflected all the then existing knowledge regarding the heart. He was, perhaps, the first to fully recognize the very common clinical connection of dilatation with simple debility and softening of the walls of the heart from anemia and retrograde changes of the tissues without obstruction to the circulation. This volume is in itself an instructive, though somewhat out of date, library on the heart. I can not, however, deal further with this retrospective view of the pathology of the heart muscle.

Balfour[10] has well said, speaking especially of the heart, that the vigor of any muscle depends on the perfection of its metabolism. In practically all cases of chronic nutritional disease the metabolism of the entire body is notoriously at fault, and the heart muscle feels, with all other muscles, the loss of vigor incidental to its perversions. We are familiar with it in the lack of force and endurance of the voluntary muscular apparatus; it is conspicuous in the muscular atony of stomach and intestines, and we have learned to look for it and recognize it as a factor of vital importance in the functional integrity of the heart. In this connection it should be remembered that the nervous system, on which all muscular tissue is dependent for trophic and motor influences, is itself equally dependent on metabolism, with all that this implies, for the proper performance of its functions, and that the heart in such conditions suffers from a perverted innervation as well.

One of the first results of this weakness, so far as the heart itself is concerned, is an inadequate systole. We know that the ventricles of the perfectly normal heart do not completely empty themselves. At the close of every systole there is a very small amount of residual blood remaining in the ventricles. The precise amount must depend on the vigor of the ventricular contraction, and must increase with progressive weakness of the cardiac muscle. In its milder grades this amounts only to exaggerated physiologic distension, and perhaps only occurs when a slight demand is made on the heart for extra work, such as a degree of exercise that would not perceptibly effect a normal heart. As the weakness increases the overdistension results from still slighter causes until, finally, in certain cases it becomes permanent and constitutes what is clinically known as dilatation of the heart.

The occurrence of dilatation is dependent on at least one other important factor, aside from weakness of the cardiac muscle, namely, the arterial resistance. The resulting intracardiac tension is subject to great variations in both health and disease, but, in the absence of organic disease involving the arteries, it is always relatively low in cases of weak heart. But even when relatively low there is considerable pressure, even in the passive state. In health it amounts to perhaps 10 to 12 c.m. of mercury; in debilitated states it may drop to 5 or even much less, but a positive pressure equivalent to several c.m. of mercury is absolutely essential to the functional integrity of the organs supplied and this pressure must be overcome by the contraction of the cardiac muscle. If the heart muscle is unable to force its contents through the arteries against this pressure, an increasing amount of residual blood remains in the ventricles and dilatation results. It is perhaps only rarely that the weakness of the cardiac muscle is sufficient to lead to a continuous dilatation while the patient is in a passive state. The overdistension occurs in paroxysms coincident with a transient rise of pressure, usually the result of exercise. Exercise always raises the arterial tension, both in health and disease, and leads to transient dilatation, which the healthy muscle can overcome but the weak muscle can not, and in weakened conditions of the heart muscle these periods of overdistension are only partially recovered from, and when this occurs repeatedly the various grades of dilatation of the heart, slight or severe, ensue. It is in reality a frequently repeated overstrain of the heart. It is, in effect, precisely what occurs when the healthy heart is overstrained, only the results follow comparatively slight causes. Overstrain of the heart is altogether a relative affair. I think it is Stokes who relates a case in which a patient with an extremely weak heart was slowly improving by absolute rest in bed, not being even permitted to wash his own face. After considerable improvement, but, before being authorized to do so, he sat up in bed and washed his own face and fell over dead. This was simply fatal overstrain of a very weak heart from an apparently very trifling cause. In another case a similar result might follow walking across the room; in a third it would follow a short run to catch a street car or by hurrying up steps; while in a perfectly healthy heart the same result could be produced by sufficiently severe and sufficiently prolonged muscular exertion, as probably occurred in the classical case of the Greek soldier who delivered his message of victory and fell over dead. Hereditary tendencies, or at least an inherent inadequacy of the heart muscle, undoubtedly has much to do with the phenomena in any given case. Some hearts are primarily defective, just as are some livers and some brains, and readily succumb to causes which would not be operative in other cases.

The pathology of the cardiac muscle in the cases under consideration is quite variable. Eichhorst[13] says that weakness of the heart muscle may cause death without any macroscopic or microscopic changes in its structure. However, this is perhaps rarely true. The nutritional disturbances incident to chronic disease lead to various alterations in the texture of muscles in the heart and elsewhere. Barrie says[12] that when dilatation occurs there is always granulo-fatty degeneration

of the heart fibers and pigmentary infiltration. In such cases Gibson[11] and others speak of an indistinctness of the striations of the muscular fibers. Probably in all the severe cases there is some sort of change more or less marked in the cardiac muscle. While it is very desirable to have as full an understanding as possible concerning the pathology of each case, it can only be determined with a certain degree of probability. It has, of course, an important bearing on prognosis, but the existence of marked degenerative processes do not bar recovery. In many cases chronic myocarditis is probably the underlying morbid condition. The existence of certain types of chronic inflammation, as well as degenerative processes in chronic nutritional disease, is quite intelligible in the light of modern pathology. These various morbid processes are the result of subnutrition and toxins. The hemoglobin coefficient is usually low and there is scant material for tissue reconstruction, while, in addition and partly as a result, there is defective elimination on the part of the heart muscle itself of its own waste products, as well as of the body in general. The retention of leucomaines and other products of retrograde changes has a still further depressing influence on the function of the heart muscle and favors the development of the anatomical changes already referred to. But, in addition to this, and especially in the class of cases with which I have personally had to deal, we have a new factor in the introduction into the circulation of bacterial toxins produced in excess in the digestive tract. These toxins probably unite with the side chains of the protoplasmic molecules of the heart muscle, just as certain metalic substances are supposed to do with more or less impairment of functional power and, finally, with the production of genuine structural alterations of the character already indicated.

In the cases in which no microscopic alterations can be found in the heart muscle the tissues are softer and more easily torn, as long ago pointed out by Walshe.[3] It can scarcely be that such a physical change can occur in the heart muscle without antecedent structural alterations undiscoverable by our present means of research.

Although not strictly within the scope of this paper, I am tempted to briefly refer to syphilis, the very extensive prevalence of which, among all classes, makes it a frequent factor in the class of cases under discussion. Syphilitic involvement of the heart is probably much more common than is recognized, and is not a very infrequent cause of weak heart, leading to varying degrees of dilatation. Aside from the gummatous disease of the heart muscle itself, and involvement of the coronary artery, there is recognized by syphilographers a syphilitic myocarditis. And there is good reason to believe that, prior to the evolution of such gross changes as this, there is a period of weakness which, in consequence of proper treatment, may never pass into the stage of structural alteration. The hearts of syphilitic patients are very vulnerable, and this cause of cardiac weakness should receive wider recognition than is at present accorded it.

In chronic gastro-hepatic disease there are some reflex nervous phenomena which should be considered in addition to the factors already mentioned. The experiments of Morel and others have shown that, on stimulation of the terminal filaments of the pneumogastric or sympathetic nerves in the gastric mucosa, or possibly of both, there is a reflex spasmodic contraction of the pulmonary capillaries, with a rapid rise of pressure in the pulmonary artery and a transient dilatation of the right ventricle. If reflex irritation of these nerve filaments is continuously produced by a pathologic lesion, Barrie[12] says it may cause persistent dilatation, which may increase until there is tricuspid insufficiency with extreme ectasia of the right ventricle. He adds, however, that its relative infrequency in gastro-hepatic disease points to an individual predisposition which may, of course, be hereditary or acquired through the operation of some of the causes and conditions that I have already considered.

It is unnecessary to occupy time in dwelling on the individual chronic diseases which occupy an etiologic relationship to the condition of the heart muscles under discussion. Among them may be mentioned leukemia, chlorosis, all the different types of anemia, either secondary or those other types which in our ignorance we call primary, chronic diseases of the digestive organs associated with subnutrition and relative failure of elimination, excessive toxic conditions, etc. These various causes act on the heart in at least four ways: First, a failure to supply sufficient nutrient pabulum to the heart muscles because of a weakening of the complicated mechanism concerned in its accomplishment. Second, through the chemical influence of retention products, which are toxic in excess, and the absorption of foreign substances, for the most part, from the gastro-intestinal tract. Third, through the partial failure or perversion of the important phenomenon of innervation of the heart muscle. And, fourth, the purely mechanical factor which is operative from the moment when the cardiac muscle is unable to make an effective ventricular contraction against the resistance offered in the arteries. Sometimes one or several of these causes will predominate, but I think they will be found to fully explain the clinical phenomena presented.

The symptoms of heart weakness and dilatation vary within wide limits. It is scarcely necessary to dwell on the clinical manifestations of fully developed and well-marked dilatation of the heart, with its well-known train of symptoms. It is more important to emphasize the fact that there can be, and frequently is, a recognizable grade of dilatation, with either an entire absence of symptoms or at least such as can be elicited with great difficulty. The earliest symptoms are simply those of a weakened circulation, and in the various types of chronic nutritional diseases, with their associated debility and slight dyspnea following a given amount of exercise, are simply attributed to the general disease present. It is not until the dilatation has proceeded to a degree which will produce valvular incompetency by enlargement of the orifices or separation of the insertions of the papillary muscles, or both, that the obvious clinical picture of heart disease with dominant heart symptoms is presented. This condition, however, is preceded by a long series of events, with any one of which, perhaps, its onward march could have been arrested if duly recognized and properly treated.

The importance of these slighter and frequently unrecognized grades of dilatation of the heart is not limited to the heart itself, but, in addition, frequently furnishes the key to the entire ensemble of symptoms, which, while having a complicated origin, are possibly based more largely on lowered blood tension than on any other single factor.

I have not attempted to make any statistical statement of the number of cases in which demonstrable grades of dilatation have been presented, as such a statement with reference to so vague and diverse a group of cases would appear to be valueless. I will

say, however, that in a very large proportion of the cases which have been able to come to my office for examination and, perhaps, subsequent treatment, such a condition of the heart has been found. I should think that possibly 20 per cent. of these patients presented demonstrable enlargement of the heart, varying in degree from an enlargement so slight as to be doubtful until verified by a decreased area of dulness under subsequent treatment, to cases so severe as to make dyspnea on very slight exertion one of the principal complaints in the case. The diagnosis is based principally on the area of deep dulness, which has, of course, to be quite accurately determined. This I do not consider difficult in the vast majority of cases. Of course where there is emphysema or excessive obesity, it becomes proportionately more difficult. Broadbent[9] says that it can not always be determined, and further adds that the so-called auscultatory percussion is of no value whatever. With the last statement I must entirely disagree. By the use of the ordinary methods of auscultatory percussion or, better, by the use of the phonendoscope, with either light percussion or friction, the borders of the heart, and especially the left, can be determined with great accuracy. I have verified the results of these examinations, both by autopsies and skiagraphs, and have the utmost confidence in them. By placing the phonendoscope in the intercostal spaces over the area of absolute dulness and making very light strokes or friction sounds gradually extending outward, the border of the heart is easily recognized. The sharpness of the line of demarkation where the transition of sound occurs is really very striking. I only mention this because there is a more or less widely spread opinion such as that already quoted from Broadbent, that slight changes in the volume of the heart can not be clinically determined with accuracy.

In the severer cases regurgitant murmurs will sometimes be found constantly present over either the mitral or tricuspid area or both. In many of the milder cases, however, where such a murmur is not heard, it can readily be produced, while in others it can be produced with difficulty, and the readiness with which it can be elicited furnishes some indication of the tonicity and recuperative power of the heart muscle. The character of the heart sounds soon becomes modified as the case progresses, the first sound losing its characteristic qualities, more and more approximating to the character of the second, and, at the same time, the interval between the second sound and the first becomes gradually shorter, approximating more and more to the interval between the first and the second, until it finally becomes practically the same.

The treatment of these cases should have in view two principal objects: first, to improve the general nutrition and correct the defects and perversions of metabolism, which are the underlying causes, which includes rational and adequate treatment of any organ or set of organs which may be at fault, among which the digestive organs stand pre-eminent; and, second, when necessary, the application of special therapeutic measures directed toward the heart.

It would not fall within the scope of this paper to make any attempt at a discussion of the multiform methods included under the first heading. It need only be said that it includes and requires adequate nutrition, which means an ample food supply properly digested and assimilated to the fullest extent possible under the conditions presented; effective elimination of the products of retrograde changes which may be unusually toxic owing to morbid perversions in the chemical processes occurring in the tissues; tonic and reconstructive medication, such as the exhibition of iron and bitter tonics where these appear to be indicated; and, finally, the best mental and physical hygiene available under the circumstances of the case.

So far as the second object of treatment is concerned, it will frequently happen that no special measures directed toward the heart will be required, especially in the milder cases. Proper rest for the nervous system and the circulation conjoined with the measures already indicated may be sufficient to restore the heart to its normal condition and size. In many cases, however, I have found such special methods of treatment not only advantageous but necessary. Where the heart is quite weak, with frequent pulse and the blood pressure low, the cautious administration of digitalis for a brief period of time has been of the greatest service to me in these cases. Other heart tonics may also be employed. Such outdoor exercise as is indicated in the case should be graduated, with special reference to the heart, and in most cases forms an indispensable part of rational treatment.

I wish now to speak of the saline carbonated baths as a means held in reserve for the severer cases or even some of the milder ones which for some reason prove intractable. I am fully convinced of their very great value after having treated a considerable number of cases in this manner. I have found, in agreement with Broadbent and others, a remarkable decrease in the area of deep cardiac dulness as a result of a single bath properly administered. In fact, I am not aware of any other possible means of influencing so immediately and directly the dimensions and tonicity of the heart. I have found the left border of the heart more than one centimeter further to the right immediately after such a bath than it was before, and have verified the findings with the fluoroscope. At the same time the pulse will drop in frequency anywhere from 15 to 30 beats, with a corresponding improvement in volume and tone. The greater part of this phenomenal change is comparatively transient, but where treatments are given daily the heart does not lose quite all it has gained, and after three or four weeks of such treatment may attain nearly or entirely its normal size and remain permanently so under favorable conditions, which means, of course, a removal of the causal factors and a continued maintenance of the general health. Gibson[11] says that it is just in this class of cases that the very best results are obtained from the Nauheim methods. I believe this is true, and have certainly had most gratifying results in properly selected cases, although it is not used, as a matter of course, as a routine measure.

With the resistance movement I have had less experience, as my patients have, for the most part, been able to resort to active instead of passive movements; and properly graduated gymnastics and outdoor exercise have appeared to me to be all that was necessary.

In conclusion, I wish to emphasize the favorable prognosis of dilatation of the heart in most cases, even the coexistence of valvular disease not necessarily constituting an insurmountable bar; its relative frequency in chronic nutritional disease, and the strong probability that the milder cases, if unrecognized and neglected, finally present all the clinical features of advanced and incurable heart disease.

PAPILLOMA OF THE SOLE.*

DOUGLASS W. MONTGOMERY, M.D.
PROFESSOR OF DISEASES OF THE SKIN, UNIVERSITY OF CALIFORNIA.
SAN FRANCISCO.

A wart is usually an insignificant affection, but when it grows in a confined space, as under the hard, thick covering of the sole, it may cause so much discomfort, it may be so persistent and so refractory to treatment and develop such an ugly appearance as even to simulate malignant disease.

It is not a frequent affection, as I have in my private practice seen only seven cases of it in about five thousand cases of diseases of the skin. In a careful search of the literature of diseases of the skin, mention has been found of only sixteen cases. But I have reason to believe that neither of my own private histories nor the literature give a true indication of the real frequency of the affection. People afflicted usually consult chiropodists and, after being treated, or maltreated, the wart disappears, either as a consequence of treatment or spontaneously. The chiropodists have a most striking name for the affection, calling it "a rose corn." This name is very appropriate to that form that looks like a callosity and, the callosity being removed, one finds a strawberry wart at the bottom of a well-like hole.

CASE 1.—The first patient who consulted me for this affection was a large, fat man, 56 years of age, whom I had been treating for eczema. He consulted me June 13, 1897, for what I thought was a corn on the right sole. The corn was very sensitive to pressure. I ordered salicylic acid plaster mull 10 per cent., and had the patient call shortly afterward, when I peeled off the epidermis. To my surprise I found a well, at the bottom of which was a wart-like vegetation. The mouth of the well was perfectly circular and nicely rounded and prominent. I reapplied the salicylic acid, removing layer after layer of the epidermis, till I had the wart well exposed, and then burnt it with nitrate of silver. I did not, however, burn it sufficiently. It is often necessary to press down the nitrate of silver stick into the hole, through the epidermis, although it is very painful to the patient. The wart in this case continued to grow until I feared it was a papillary epithelioma of the sole. After the second, more thorough, burning, however, the affection got well and never returned. In this case there were no other warts seen or complained of in any other region.

CASE 2.—Sept. 5, 1898, a man, whom I had under my charge seven years before for syphilis, eczema and herpes simplex, consulted me for what appeared to be a corn under the anterior part of the sole of the foot. The patient had had it mistreated by a chiropodist and, when he came under my care, was suffering much pain. His case was an almost exact repetition of the former one.

CASE 3.—On March 2, 1899, a man, 28 years of age, consulted me on account of a painful wart on the plantar surface of the ball of the left toe, which had appeared three months before. The patient was also suffering from eczema between the toes and from premature baldness. The papilloma disappeared under the same treatment as that employed in the two former cases.

CASE 4.—On April 27, 1900, a woman, about 30 years of age, consulted me on account of warts on the anterior portion of the sole of the foot. There was one large, flat, round wart, about one inch in diameter and looking like a corn, situated on the ball of the left great toe. This wart was not painful, and on examining it with a lens dark red strings could be seen running up through it. These looked like the capillaries of a soft wart in which the blood had coagulated. It looked entirely different from anything I had ever seen in the way of warts growing under the thick, hard epidermis of the palms or soles. As much of the top was shaved off as was possible without causing too much bleeding. A salicylic acid plaster mull was applied. By May 7, 1900, the large wart had separated out into several individuals, having white plates of epithelium over them, and the red strings above mentioned were now white, probably bleached out by the salicylic acid. This lesion therefore was not one wart, but a bunch of several warts. On this date two other warts were found, one in the very center of the anterior part of the left sole, and two others just in front of the original lesion on the ball of the great toe. June 20, I had the patient use at night salicylic acid, ʒiiss, collodion flex., ʒii, and in the day time plaster mull. By June 27, two months after she first came to me, the epidermis was thinned down enough to permit of cauterization with nitrate of silver. Shortly after this the warts disappeared.

This was one of the most obstinate cases I have ever treated. The epidermis implicated in the wart was soft, spongy and resistant to the knife.

CASE 5.—Sept. 24, 1901, a boy, aged 14, consulted me for hyperidrosis of the right heel; the heel was reddened, and in the hollow of the foot there were a few rusty papules. October 30, I first noticed on the right heel two perfectly round holes, each about 2 mm. in diameter. These holes were filled with a perfectly white detritus, and at the bottom of the holes there were a few red, prominent papillæ. The epidermis was shaved down as close as possible and the papillæ were burned with nitrate of silver and a 5 per cent. salicylic acid plaster mull was prescribed.

Jan. 21, 1902, there was still a little remnant of one of the lesions, which was burned with nitric acid, after which the trouble disappeared.

This patient was an immensely overgrown boy and very stout. He was the only son of a doting mother, who was anxious about his health, because he ate so little at meals, but between meals, his sister told me, he ate constantly, a fact which his mother did not know, or possibly chose to ignore. Everything in the way of fruits, cake, candy and lump sugar disappeared in a miraculous way. These facts are mentioned as the consequent overnutrition very probably had something to do both with the hyperidrosis and the papillomata. He was just such an individual as one would expect to get seborrheic eczema.

CASE 6.—Jan. 21, 1902, a boy, 15 years of age, consulted me in regard to papillomata of the plantar surface of the right heel. The first one appeared one year before, and when he consulted me there were about a dozen visible. As much of the epidermis was shaved off as was possible without causing abundant hemorrhage, and the exposed warts were burned with nitric acid. An ointment composed of salicylic acid 20 gr., lanolin and vaselin each half an ounce was prescribed to be worn constantly. By Feb. 8, 1902, this ointment had peeled off the epidermis down to the quick, and a vast number of papillomata were uncovered. The whole heel presented a worm-eaten appearance, showing irregular, steep-edged holes, filled with epidermal detritus. All exposed papillomata were again burned with nitric acid. By February 26 everything looked well.

CASE 7.—Aug. 2, 1902, a man, about 19 years of age, consulted me in regard to what appeared to be a filamentous wart on the anterior surface of the right sole. The epidermis was peeled down as far as possible, the wart was burned with nitrate of silver and a salicylic acid ointment (30 gr. to the ounce) was prescribed. By August 6 the wart had died down or retracted so as to leave a circular hole about one-quarter of an inch in diameter, filled with a crumbly white mass, and showing the diminished wart at its bottom. A stick of nitrate

of silver was pressed firmly into the hole, the same ointment was applied and in a couple of weeks he was entirely well.

Traumatisms, such as direct blows, heavy marching, nails sticking up in the sole of the boot, inequalities in the sock, or in the sole of the boot, have all been given as causes of plantar warts. Lenoble[1] attributed the affection in his case to heavy marching. Gorju[2] reported an instance consequent to walking on cannon balls. In the cases reported in this paper no history of traumatism was present. In three of the cases there was eczema, in one of them herpes, and in one hyperidrosis. All of these may indicate an irritable state of the skin favorable to the development of papillomata, but it is noteworthy that there were no warts found on any other part of the surface in these cases. William Dubreuilh, who has written by far the best paper on this subject, says that neither himself nor Bargues, whom he quotes, has ever found coincidence of warts of the soles and of the palms.

A wart on the sole usually first appears as an abnormally painful, large, lenticular, elevated callosity. After removing the hard epidermal covering, a well-like orifice is exposed with the papilloma in it. This appearance is what has given rise to the name "rose corn." The depth of this well-like hole is one of the surprises of the affection. Pain may be present for quite a long time before the appearance of the callosity. In a case reported by Gorju[2] pain was present for two months before the callosity was noticed.

Warts of the sole may also appear as filamentous threads growing up through a soft, white, elastic epidermal mass, as in Case 4.

A papilloma may also look like a soft tumor, implanted like a cork in the epidermis and emerging from a circular orifice and spreading out on the surface like the cover of a pot.

Dubreuilh says that the pain of the warts, like that of corns, is influenced by changes in meteorologic conditions. I do not remember any of my patients to have complained of this, but, as I never inquired, it may have been present.

Warts of the sole, as elsewhere, may disappear spontaneously; they may, however, last for years and cause a vast amount of pain and inconvenience. Lenoble reported a case where the tumor had begun twenty years before the demonstration of the patient before the dermatologic society. Melchior Robert had two cases, each lasting two years.[3]

Dubreuilh recommends curetting as the most rapid and effective treatment. Although the curette may have very little influence on the hard, resistant walls of the cavity, this does not matter. The essential is to clear out the contents, which can be readily done. The profuse bleeding can be stopped by pressure, and the wound is to be dressed according to ordinary surgical principles.

Bargues recommends frequent cauterizations with pure nitric acid. The objections to cutting out such growths are the difficulty of reaching the base through the thick epidermis, the great pain occasioned by the cutting and the liability of leaving a cicatrix in a situation where a scar is very undesirable. All these disagreeable features may be avoided by first softening the hard epidermal covering, and so exposing the part to any treatment, such as would be applicable to warts occurring on the thin skin of other parts of the cutaneous surface.

THE MANAGEMENT OF FEVER IN GENERAL.

AUGUSTUS A. ESHNER, M.D.

Professor of Clinical Medicine in the Philadelphia Polyclinic; Physician to the Philadelphia Hospital; Assistant Physician to the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases; Physician to the Hospital for Diseases of the Lungs at Chestnut Hill.

PHILADELPHIA.

In the present state of knowledge fever must be looked on as a symptom-complex resulting from some derangement of the bodily chemistry, from some disturbance in metabolic equilibrium, which may be brought about in a variety of ways. The causative factors may be generated within the body, or they may be introduced from without, in either event operating through the agency of the nervous system. Thus, fever may result from the retention within the body of the excrementitious products of retrogressive metamorphosis, as in cases of uremia; in consequence of profound changes in the blood, as in cases of anemia; from exposure to intense heat, as in cases of insolation; and it occurs readily in children—in whom the nervous system is notoriously unstable—on slight provocation, such as gastrointestinal derangement and even emotional influences. Most commonly, however, fever is due to changes secondary to infective processes—in other words, to the toxic effects of the products of bacterial and cellular activity.

Of the ultimate mechanism of the febrile process nothing definite is known. It is a well-recognized biologic fact that plants and animals are provided with the means for adapting themselves to variations in the surrounding temperature, so that they produce or conserve a greater amount of heat when exposed to low, and a lesser amount when exposed to high, temperatures. Loss of heat in man is counteracted by contraction and favored by dilatation of the peripheral blood vessels. It is reasonably certain that this regulatory power is lodged in the central nervous system, and it is believed that it is under the control of a hypothetical thermotaxic mechanism, which maintains the relations between heat-production and heat-dissipation under varying conditions.

The most distinctive and the most constant feature of the febrile process is elevation of temperature. Although it is customary to attempt a differentiation between fever and pyrexia, it is a question whether such a distinction can be successfully made. It is true that occasionally certain conditions ordinarily febrile, such as typhoid fever, typhus fever, septicemia and scarlet fever, are unattended with pyrexia, but under such circumstances it may be that the pyrogenic substances usually produced are not generated or are not absorbed, or that their effects are neutralized by antipyrexial substances generated within the body. Nevertheless it is doubtful whether we can recognize a febrile process in the absence of elevation of temperature, or if pyrexia occurs in the absence of fever. Those who endeavor to maintain a distinction between fever and pyrexia take the ground that elevation of temperature of non-febrile origin is due to either increased heat-production or diminished heat-dissipation, or to both, while the elevation of temperature attending the true febrile process is due to an elevation of the heat-regulating mechanism to a higher level without alteration in the relation between heat-production and heat-dissipation. It has been thought that elevation of temperature in the presence of infectious diseases is a conservative process, perhaps having antibacterial or antitoxic value, but as to the accuracy of such a view the evidence is not conclusive.

Other symptoms of the febrile process, such as accelerated action of the heart, increased frequency of respiratory movement, circulatory changes, alterations in secretion, assimilation and metabolism and in function generally, may be due to the same factors as the underlying morbid state or to the pyrexia, or to a combination of the two. The problems, therefore, that confront the clinician in the management of a patient exhibiting fever comprise the removal of the causative and underlying factors in so far as this is possible, and the restoration of the metabolic equilibrium, whose derangement is manifested in the various disorders of function. Often little or nothing can be done to fulfill the first indication, as the underlying morbid process is a specific and self-limited one insusceptible of abortion or abridgement, but unless there be some contra-indication, some form of elimination or evacuation or attenuation may with advantage be instituted, such as emesis, catharsis, diaphoresis, diuresis, enteroclysis, hypodermoclysis, intravenous transfusion. Through emesis irritants will be removed from the stomach and infection by way of this organ averted or absorption of poisonous substances from its cavity prevented. Catharsis will perform the same office for the intestinal tract, and besides exert a derivative effect. A like statement may be made with regard to diaphoresis for the skin, and with regard to diuresis for the kidneys, while by means of intestinal, subcutaneous and intravenous infusion poisons circulating in the blood will be diluted, and their elimination through the emunctories expedited, while a useful stimulating influence will be at the same time exerted.

With the aid of the measures named it may at times be possible to remove the primary cause of disturbance, but even when this can not be done we may be able in this way to mitigate the severity of its effects, and thus in part contribute also to the fulfilment of the second indication, namely, the restoration of the metabolic equilibrium and the correction of disordered function. Reduction of temperature may be indicated when the pyrexia is excessive, or has been unduly long continued. It is best effected by the application of cold, wet or dry, in the form of the tub bath, the sponge bath, the sprinkle, the affusion or compress, the spray, the coil, the ice bag or ironing with ice. Antipyretic drugs are as a rule not necessary, while their use is at times attended with danger. To sustain the respiration and the nervous system, alcohol, aromatic spirit of ammonia, strychnin, digitalis, strophanthus, caffein or atropin may at times be needed. Should delirium and restlessness persist despite such treatment, bromid, chloral or morphin may be administered cautiously. The diet should be simple, bland, nutritious, easily assimilable, including milk, broths, eggs, beef juice and similar articles. Cracked ice and cool water or lemonade or orangeade and the like may be given with reasonable freedom, preferably in small amounts frequently. A daily movement of the bowels should be secured, if necessary by means of enemata or by the cautious administration of calomel followed by a saline.

Statue of Pasteur at Chartres.—The portrait statue recently unveiled at Chartres deserves more than a passing mention, as it is the work of a physician, anatomist and sculptor, a native of the town, Dr. P. Richer, now of Paris. The marble bust of Pasteur rises above a bronze bas-relief depicting scenes in the campaign against anthrax in sheep by the inoculations originated by Pasteur which have saved the chief industry of the province from destruction. The total height of the work is nearly fourteen feet, while the base is twenty-two feet in diameter.

EARLY EYE SYMPTOMS IN A CASE OF MYASTHENIA GRAVIS.

CASSIUS D. WESCOTT, M.D., AND BROWN PUSEY, M.D.
CHICAGO.

In a thesis[1] for the degree of M.D. at Cambridge on the subject of "Myasthenia Gravis," Chas. S. Myers records the undoubted and completely studied cases of this disease. His list contains 22 cases; in 12 there was partial or complete external ophthalmoplegia, in 9 diplopia, in 14 ptosis. These findings and the fact that in 13 of the 22 cases in Myers' list the paralyses of the eye muscles were of the very early symptoms that showed themselves, suggests the publication of the history of the eye symptoms of the following case.

Fortunately, our case has not been completely studied (Myers includes only cases that have come to autopsy), but it has gone far enough to emphasize the fact, which agrees with the findings of Myers and which has been pointed out before, e. g., in the recent article of Sir William Gowers,[2] that the eye symptoms may be the first complained of. The early diagnosis of the disease is certainly desirable, and may be very important, because of its bearing on treatment. It is reasonable to suppose that the chances for recovery will be favored by an early diagnosis, for suggestions have come regarding treatment as our knowledge of this obscure disease has increased, and cases have been reported in which the patients appear to have recovered. The following is an abstract of our notes:

Nov. 6, 1899. W. E F., male, aged 20, a telegraph operator by occupation. Complains of red and uncomfortable eyelids, of blurred and double vision; when he looks at anything, it at first appears double, and he has to close one eye to see. The eyes have given trouble during the past summer. There is a chronic conjunctivitis. L V.=6/9; R. V.=6/7. Esophoria 22°. L. hyperphoria 8°. Accommodation unaffected. Refraction under homatropin and cocain:

L. V.=6/5 with —1.00 D. Sph. —0.50 D. Cyl. Ax. 25°.
R. V.=6/5 with —0 75 D. Sph. — 0.25 D. Cyl. Ax. 120°.

The above correction, less 0.25 D. Sph., was given for constant use, and the patient was asked to return within ten days or two weeks for observation.

Nov. 17, 1899.—Patient states that he is improved, but still complains of blurred vision. Examination shows esophoria 12° (a decrease of 10°), left hyperphoria 8°. Encouraged by the decrease of esophoria, the patient was told to continue the use of the glasses and to report again in two weeks.

Dec. 8, 1899 (one month after the first examination). The patient states that he can work all day and until midnight, and that there is no blurring of the vision. No esophoria, left hyperphoria 3°.

Jan. 4, 1900.—Has been overtaxing the eyes, and they are red and weak again. Has some double vision at times. Exophoria 1°; right hyperphoria 3°.

The patient did not return again for two and a half years.

July 3, 1902.—Recently has had double vision, and "focusing the eyes is difficult." Exophoria 11°, no hyperphoria. Accommodation normal, and the pupils react normally. Vision with glasses, left eye and right eye, 6/9. Has not noted anything wrong in his general condition. Advised re-examination of the refraction.

Aug. 6, 1902.—The patient returns complaining of the same symptoms that troubled him one month ago. Refraction under homatropin and cocain:

L. V.=6/5 with —1.62 D. Sph. —0.50 Cyl. Ax. 60°.
R. V.=6/5 with —1.50 D. Sph. —0.50 Cyl. Ax. 110°.

The above correction, less 0.37 D. Sph., was given for constant use, and the patient was asked to return shortly.

1. Journal of Pathology and Bacteriology, 1902, September, vol. viii, No. 111, p. 306.
2. Myasthenia and Ophthalmoplegia. British Med. Jour., 1902, May 24.

One month and twenty days later he returned, when there was paralysis of convergence and slight ptosis of the left upper lid. The pupils reacted normally; the accommodation was not affected, and the patient said that he could work at his desk very comfortably when one eye was closed. The fundus was normal. He was referred to Dr. H. N. Moyer, who made the diagnosis of myasthenia gravis, and exhibited the patient before the Chicago Neurological Society.

Although the findings in this case will be more completely published later, it seems appropriate to call attention here to some of the facts pointed out by our notes. The most important one is that already cited, that the eye symptoms in this disease may be the first signs of trouble. Of course, this is assuming that our patient was afflicted with myasthenia gravis when he complained of double vision in November and December, 1899. Even if it is not granted that the disease existed at that time, it seems safe to venture the opinion, in the light of the after-history, that as marked a variation in the muscle balance as this case showed between Nov. 6 and Dec. 8, 1899, must attract unusual attention and be carefully studied, and, if possible, satisfactorily explained.

The absence of involvement of the muscles of accommodation in September, 1902, (when he could work at his desk very comfortably if one eye was closed) is interesting. Based on observations up to that time, this case agrees with the findings of Myers, who notes the absence of involvement of the ciliary muscles in the cases studied by him. The possibility of the escape of the ciliary muscle in this disease, and the fact of the difference histologically between it and the external muscles, could well give rise to some speculation. This, however, is upset by Gowers' report, in whose case there was interference with accommodation, and the same is now true of our patient.

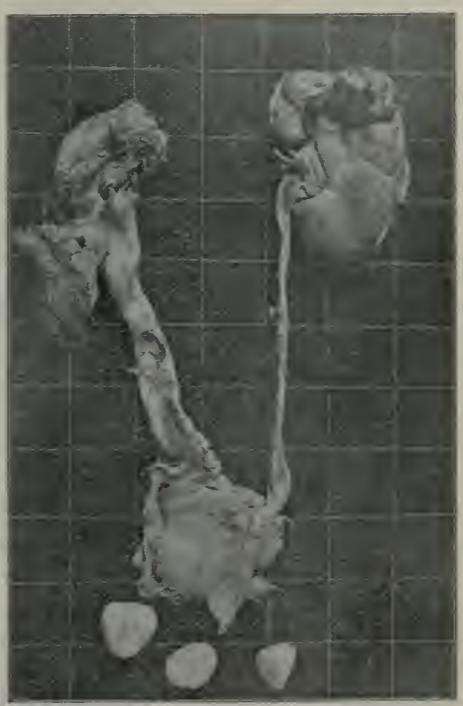
The variation in the refraction may have some significance. According to our examinations, which were made with homatropin (homatropin hydrobromate, gr. x; cocain hydrochlorate, gr. x; water, ℥i, of which mixture a drop was put into each eye every five minutes for thirty minutes, and the examination was made forty-five minutes after the last application), the myopia increased 0.75D, and the investigation of the subject brings a letter from the patient, which says: "In early life I seemed to be able to see fully as far as anyone, and, so far as I know, my vision was not shortened until just previous to my first call on you." It will be recalled that at the time of the first examination there was slight myopia. If there is any relation between the disease and the myopia, it would be curious. How is it to be explained?

The cessation of symptoms in this case for over two years calls attention to one of the three signs, which Myers says may be described as pathognomonic of this disease, viz.: exacerbations and remissions shown in its course, and warns us to be careful about pronouncing a recovery in any given case.

Clinical Report.

PYONEPHROSIS WITH A KIDNEY-COLON FISTULA.

GEORGE E. McLAUGHLIN, M.D.
Pathologist to Christ Hospital.
JERSEY CITY.



History.—The patient, a man, aged 37; white; occupation railroad conductor; entered the service of Dr. Gordon K. Dickinson at Christ Hospital, Jersey City, for operation, with a diagnosis of vesical calculus.

Family history was negative. The patient had the usual diseases of childhood; twenty-five years ago an attack of typhoid fever; five years later a gonorrhea and a slight stricture of the urethra. He uses tobacco and alcoholics in moderation. Two and one-half years ago he began to complain of a burning sensation, and often severe pain on micturition, with interference to the free passage of urine, and at times a sudden stoppage during the act of passing it.

He states that he has never passed blood in his urine. Lately he noticed that he was losing weight and appetite. He states he has had no chills or fever since the attack of typhoid fever 25 years ago. He gives no history of constipation or diarrhea, and the evacuations of the bowels are regular. His temperature for the three days previous to operation was normal and subsequent to it not above 100 degrees.

Operation.—A suprapubic lithotomy was performed and three calculi weighing collectively 168 grams were removed. There was no suppression of urine subsequent to the operation. The third day the patient died.

Necropsy.—All the organs, with the exception of those later mentioned, were normal, save that the intestines showed some slight adhesions. The bladder wall was much thickened. The interior of the viscus had a ribbed appearance. The veins were somewhat prominent and the mucous membrane was

of a yellowish color, and covered with shreds of mucus and urinary salts. The right ureter measured one inch and a half in diameter, and was of a leathery consistence. The left ureter was about three times the usual size, being somewhat tough to the touch.

The right kidney was normal in size and was adherent at its lower end to the colon. On sectioning it proved to be a typical pyonephrotic kidney, only a thin wall of kidney structure, possibly one quarter of an inch thick, remaining. It was connected, as shown in the illustration, with the colon, by a fistulous tract one inch long. The left kidney was much enlarged, the capsule non-adherent, and projecting from its surface were three cysts, the one shown in the illustration at its upper portion being two inches in diameter. All these cysts contained a urinous fluid. This kidney showed a chronic diffuse nephritis and contained two half-inch calculi in its pelvis.

A METHOD OF RENDERING ULTRAMICROSCOPIC PARTICLES VISIBLE.

During the last few years bacteriologists have come to attribute a rapidly increasing number of diseases to microbes that are too small to be seen with our best microscopes.[1] With these instruments and the ordinary method of illumination Helmholtz and physicists in general tell us that it is not possible to get a clear image of an object that is less than ¼ micron in diameter. Recently, however, two German physicists, Siedentopf and Zsigmondy[2] have perfected an apparatus by means of which they are enabled to see particles having a diameter of 0.005 micron or even less. They make use of the best microscope that can be furnished by Zeiss and illuminate the preparation to be examined with a cone of intense sunlight or light from an electric arc. The light is concentrated by means of a system of condensors, and the vertex of the cone thus formed strikes the axis of the microscope at right angles and illuminates the preparation in such a manner that none of the light enters directly into the objective. Under these conditions ultramicroscopic particles lying in the field of the objective will send enough light through the microscope by refraction and reflection to give a clear image. These images, however, are merely luminous points, the brilliancy of which varies directly with the size of the particles. In order that two particles lying side by side may give two distinct images it is necessary that they be placed at least ¼ micron apart. Particles of considerable size, 0.1 micron or more in diameter, give two images, one reddish and the other greenish yellow. From the appearance of these images it is not possible to judge the size and shape of the particles, although the larger particles are more brilliant than smaller ones.

Further details may make this a little plainer: The observer and his instrument are placed in a dark room, in one of the walls of which is a small opening provided with an iris diaphragm. By means of a heliostat placed outside, a ray of sunlight, or electric light, is reflected horizontally into the dark room through the opening in the iris diaphragm. This ray of light strikes a rather large lens, which throws a real image of the sun on a small slit copied from the microspectroscope of Engelmann. The size of this slit can be accurately adjusted by two micrometer screws. It can be varied from 0.05 mm. to 0.50 mm. in width by 0.1 mm. to 2.0 mm. in length and must vary according to the size of the particle to be examined. Behind the slit is placed a second iris diaphragm, a polarizer, and then a second lens, which forms an image of the slit one-quarter its actual size. Behind this image is placed a microscopic objective (AA of Zeiss), which acts as the last condensor and forms a second image of the slit, 1/9 as large as the first one, or 1/36 as large as the slit. This small image falls on the preparation to be examined and intensely illuminates a field about 1.5 microns deep by 3 microns wide. A few additions must be made to the microscope. For the examination of solids a small additional stage 2 by 4 cm. is fastened to the large stage of the microscope stand. This miniature stage can be moved up and down by means of a fine screw and thus enables the operator to bring his preparation into the path of the illuminating rays. For the examination of liquids the inventors have devised a small container which can be screwed to the objective. This brings the first lens of the objective in contact with the liquid and obviates all focusing. Provision is made for moving the liquid and thus bringing different particles into the field of study. The sides through which the light enters and leaves the container are best made of quartz which has been deprived of its double refracting quality by melting.

The authors of the memoir have already carefully studied the small particles of gold that are found in glass which has been colored ruby red with a small quantity of this metal. With the ordinary illumination and the highest magnification obtainable with a Zeiss microscope this glass appears perfectly homogeneous. By using the intense illumination obtainable with their new apparatus, each individual particle becomes visible as a minute luminous point. The size and weight of these particles can now be approximately determined in the following ingenious manner. The amount of gold in 1 cu. mm. is determined by chemical analysis, = W mg. The number of particles in a known bulk of glass is determined by counting and from this may be calculated the number in 1 cu. mm., = n. It now follows that the weight, w, of each particle is $w = W/n$. The specific gravity of gold is about 20, and hence the volume, V, of each particle is $V = W/20n$ cu. mm.

The authors have also begun a study of colloidal solutions and Mouton[3] has suggested the use of the apparatus in the study of bacteriology. In order that a transparent medium, containing ultramicroscopic particles, may lend itself for examination it must fulfill the following requirements: 1, The particles must not be less than 5 microns in diameter; 2, they must be at least 0.25 micron apart; 3, the index of refraction of the particles must be different from that of the medium in which they are suspended. Nothing has as yet been done in the study of ultramicroscopic organisms, but, as Mouton suggests, much is to be expected from this new field of investigation. So far the best evidence of the existence of pathogenic agents too small to be seen is furnished

by the results of filtration experiments. In a large number of animal diseases of unknown etiology the virus has been found to remain active after passing through solid filters that ordinarily hold back even the smallest known bacteria. So far extreme minuteness of size is the most satisfactory explanation of such phenomena. If the method reviewed in the foregoing proves of service in the study of etiology, we shall have a further and striking example of the fact that progressive medicine is largely dependent on the application of physics and chemistry to the study of disease.

DANGER FOR AFTER-DINNER SPEAKERS.

The importance of the study of blood-pressure in pathologic conditions has become generally recognized, but its physiologic variations are hardly of less interest. There are some conditions, not directly pathologic in themselves, but readily made so, in which variations of this factor may have a supreme importance. In an article in the *Lancet*,[1] and abstracted in THE JOURNAL,[2] Dr. George Oliver describes the periodic variations of blood-pressure, especially its increase, and the factors which produce this increased pressure. He finds that the digestive wave of increased blood-pressure is a predominant one, and that it is only temporarily affected by exercise, temperature, etc. There is a uniform rise after eating of some 12 or 18 c.c. of mercury, as shown by the hemodynamometer; the upward rise is rapid, occurring within an hour or little more, while the decline is gradual, and lasts until nearly the next meal time. Thus the rise after a moderate meal is less than after a full one, but the fall occupies about the same time in either case. It is a little surprising at first thought that a rise of blood-pressure should occur simultaneously with the congestion in the splanchnic region attendant on digestion, but Oliver shows that there is a systemic congestion with the splanchnic dilation, with increased peripheral arterial tonus, and it is probable that this plays a physiologic part in the nutrition in causing, as he points out, concurrent exudation into the tissues of nourishing fluid expressed from the blood into the interstitial spaces. The pathologic or semi-pathologic significance of this fact is that of the danger of aggravating the normal physiologic blood tension into a pathologic condition by other factors which may aggravate the tension, such as mental or physical work.

It has long been known that a man is not at his best for hard mental work directly after a hearty meal, but the real dangers of work under such conditions are perhaps hardly appreciated. The tension is increased not only in the arteries of the body, but also, in all probability, in those of the brain, and this makes it easy for a weakened point to give way. The still unsettled question whether or not vasomotor nerves exist for the cerebral arterioles here suggests itself with the consequent queries as to the regulation of the cerebral circulation. It certainly does not appear that brain hypertension is materially relieved by any splanchnic diversion.

We recently have had a striking instance of death from apoplexy occurring in a prominent physician while making an after-dinner speech, and the notable death of Hon. William Windom a few years ago under similar circumstances will be remembered; and still other cases might be mentioned. The dangers from this cause have not been recognized, but when we remember that these public banquets involve a pretty hearty ingestion of food and a consequent rise of blood-pressure, it need not be wondered at that sudden deaths from "apoplexy" during after-dinner speeches are often recorded.

Apoplexy is a well-known possibility of mental strain; the weak point may be unknown to the subject himself and not revealed by any objective symptoms. The individual may have passed a life insurance examination successfully only a short time before, as is reported to have been the case with the physician above referred to, but the special stress becomes too strong for some point of weakness, and the result is fatal. It is not work, whether mental or physical, that kills. Intellectual workers, as a rule, are among the longer lived, but special stress under certain circumstances, such as post-convivial occasions when the normal tendency to rise of blood-pressure in the peripheral circulation is most marked, may be disastrous. This danger of mental effort directly after eating is one that possibly needs to be emphasized.

We do not wish to attribute too much importance to the idea, but it is one that is based on physiologic facts, and, therefore, theoretically at least, worthy of attention. It might, perhaps, be well from a hygienic point of view—and possibly from other points of view—if after-dinner speaking were dispensed with.

THE CONTROL OF MALARIA.

Based on the facts that the diagnosis of malaria can be made by microscopic examination of the blood, and that the malarial parasites are destroyed by the proper, continued administration of quinin, Koch and his collaborators instituted a systematic campaign toward the complete eradication of malaria in several more or less well circumscribed districts. They assumed that the malarial parasites can live only in mosquitoes and human beings. If the truth of this assumption be accepted—and there is no reason to question it—it follows that it becomes possible to eradicate malaria in either one of at least two ways, namely, either by destroying the malaria-carrying mosquitoes, thus preventing the parasites from multiplying and infecting new patients, or by securing such control of the malarial patients in a given locality that all the parasites in their blood are destroyed by the prolonged use of quinin, thus again preventing further multiplication of the infecting agent.

It is the latter method that Koch has put into practice, and the reports[1] on the work so far indicate that the results are satisfactory. Certain well-defined areas

1. June 13.
2. July 4, p. 63.

1. Zeitschr. f. Hyg. u. Infektionskr., 1903, xliii, Heft 1.

infested with more or less malaria were selected and placed under the supervision of competent men to look after the details. Thus an island, owned by one man, and containing a population of a few hundred people, a certain percentage of which generally suffered from malaria, was placed under the complete control of Professor Frosch. First systematic blood examinations were instituted and every case of malaria thus revealed was subjected to a thorough treatment with quinin, the administration of which was continued for three months after the active symptoms had subsided. Naturally, this procedure was repeated, and with the result that at the end of two years the malaria was destroyed, at least for the time being. Other reports show that in this way it is possible to greatly limit the disease, even in places where the population is more actively fluctuating, and in which the liability of the introduction of new cases of malaria is much greater. In these experiments—for experiments they were, though on a large scale—no special precautions were taken against the mosquitoes.

It would seem that in order to render a region permanently free from extensive malarial outbreaks it would be desirable to institute also measures looking to the destruction of mosquitoes, as recommended by Ross especially. Of course, if there are no malarial parasites in the blood of the inhabitants of a community then there can be no danger of mosquitoes carrying the disease to others. But so long as there are present the proper mosquitoes (anopheles) the immigration of new cases of malaria, which it might be impossible to prevent, may become the starting point of a new crop of malaria. Koch's method appears to be perfectly practicable, however, and the results now published show what great work can be done to limit a disease when its mode of dissemination and nature are so thoroughly understood as is the case with malaria. In order to carry out successfully undertakings of this kind it is necessary to perfect comprehensive organization under expert guidance, and to follow out the principles laid down with the most conscientious attention to details.

ROTATION OF HOSPITAL SERVICES.

In his address as chairman of the Section on Practice of Medicine at the New Orleans meeting of the Association,[1] Dr. Thayer refers to some of the evident shortcomings of the majority of our public and semi-public hospitals. He says that the most serious hindrance to advance in clinical study and teaching is the prevalent custom of rotation of hospital services.

Probably no competent, thoughtful medical man can question the force of this criticism. The first requisite for systematic clinical teaching and study is continuous, permanent service. Nothing but perfunctory, routine work can be expected when the chief of a service changes every three to six months. In business undertakings of all kinds, in schools and other institutions such rotation of service does not obtain. It exists in so many of our hospitals on account of the fact that physicians give their time and service to the hospitals without any direct compensation. The rotating service is a makeshift to lessen the individual burden.

If our hospitals are to grow in usefulness and develop progressively this makeshift must give way to the fully organized services with permanent chiefs and graduated staffs of assistants down to the interne and clinical clerk, as outlined in Dr. Thayer's timely address. The advantages of this plan to all interests concerned—the patients, medical teaching, medical investigation—are so evident and have been so often emphasized in these columns that it need not be dwelt upon in detail at this time. This is the day of organization in all lines of work of general importance. Our Association is passing through this stage in its development with so greatly increased a usefulness that it already may be pointed out as an object lesson to be followed in other directions of vital importance to medicine in our country. The next order may well be the earnest planning for a thorough reorganization of the hospital services. In every large city of the United States are public and semi-public hospitals in which the work suffers from lack of adequate organization to such an extent that conditions in many places really can not stand with credit even hasty investigation.

The first step in this advance must come from the medical profession itself. It is not creditable to a great profession like ours that its members permit themselves to be party to slipshod methods of hospital work merely because politicians and lay managers will not or do not know enough to institute rational principles into the hospitals in their charge. Our students suffer under the present system because of the great lack of opportunity to study disease in its manifestations in the living and the patients in the hospitals suffer because they do not receive the best care and treatment, to say nothing of the more indirect but far-reaching evils that must follow the sending out each year of so many hundred admittedly unqualified young men and women to practice medicine. We hope that continued agitation of this subject soon will awaken the altruistic spirit that ever must guide the medical profession, and that systematic efforts be made to improve the present conditions in our general hospitals.

THE DANGERS OF GELATIN INJECTIONS.

Since gelatin injections were first recommended for the control of severe hemorrhages in various organs, and for the treatment of aortic aneurism, they have been used quite extensively. Much has been said in favor of this method, but several deaths have resulted. The fatal results were due to such complications as septic thrombosis, phlegmons, malignant edema, and particularly to tetanus.

Several communications have recently appeared which again strongly emphasize the dangers connected

1. The Journal A. M. A., July 4, 1903, p. 1.

with the subcutaneous injection of gelatin. Chauffard[1] reported a fatal case of tetanus following a gelatin injection, and states that seventeen similar fatal cases have previously been placed on record. Dieulafoy[2] a few weeks later reports another instance of fatal tetanus developing after a gelatin injection given to control a severe tubercular hemoptysis, and he adds four more cases not included in Chauffard's statistics, bringing the total number of such deaths to twenty-three.

Quite an elaborate study on the dangers and the therapeutic value of gelatin injections has just been published by Doerfler,[3] who has twice lost patients from tetanus following subcutaneous application of gelatin. In one instance the method was resorted to to control a severe postpartum hemorrhage, in the other case to stop a tubercular hemoptysis.

It is now well known that fatal tetanus following gelatin injections is almost universally due to the introduction of tetanus spores with the gelatin in which they were contained. Levy and Bruns obtained tetanus bacilli from eight out of thirteen samples of gelatin examined. It was formerly believed that the spores of the tetanus bacillus are killed by an exposure during eight minutes to streaming steam at 100 C., but the authors quoted have shown that even after thirty minutes' exposure some tetanus spores survive, and only after thirty-three minutes were all samples of infected gelatin so exposed found absolutely free from tetanus germs. According to Forster and Brehmer larger masses of gelatin must be exposed forty minutes to a temperature of 100 C. to 120 C., and this after a preliminary warning, before all tetanus spores are killed. Many of those who have used gelatin injections have not been aware that it is necessary to so extend the period of sterilization.

In quite a number of fatal cases of tetanus following gelatin injections it was subsequently demonstrated that the gelatin used contained tetanus bacilli or spores. In other cases the sterilized gelatin left was found free from living tetanus spores. We understand now that the sterilization was insufficient, and while it may have made one part of the gelatin prepared free from tetanus spores, it left them alive in other portions.

Doerfler states that prolonged and energetic sterilization does not at all interfere with the therapeutic value of gelatin, and that if indeed sterile it is absolutely void of any danger. He concedes that the great hopes placed in gelatin injections in the treatment of aortic aneurism have not been realized, but that it has done excellent service in tubercular hemoptysis, or pulmonary hemorrhage from other causes, in intestinal, renal, vesical and uterine hemorrhages, in hemophilia and in melena neonatorum.

NATHAN STRAUS' WORK IN CHICAGO.

The philanthropist, Mr. Nathan Straus, who has made famous Straus' milk throughout New York City, has transferred his activities to Chicago, and has donated a milk pasteurization plant to the Children's Hospital Society of that city, giving its installation his own personal attention. A few such persons using their surplus wealth for the public good in this discriminating manner could materially affect the infant mortality in many of our crowded urban centers. It is to be hoped that others will follow his example, if not in this in similar lines.

THE "HERB KING" GONE WRONG.

An irregular practitioner calling himself the "herb king" was recently arrested in a California town for practicing without a license, and inaugurated a not uncommon but peculiar defense. He had a number of his patrons, or those who signed as such, many of them of the sympathetic softer sex, publish a card in the local paper saying that they had received benefit from his treatment when regular physicians had failed to relieve them, and that some of the signers owed their lives to his skill. They recommended his medicines, and alleged that his prosecution was wholly unwarranted. The sequel came a few days later, when he was again arrested and held in heavy bail for a criminal assault on one of his female patients, whether or not one of the signers or only one duped by their recommendation the record does not state. Such are the ways of the quack.

RADIUM AND CANCER.

The suggestion offered in our editorial some months ago[1] that the radium radiations would prove of value in malignant disease appears to have been realized. A cable press report from Vienna at the end of last week announced the radical cure by a series of exposures to the rays of the new metal radium of a patient 61 years of age who had long suffered from cancer of the upper lip which had finally invaded the palate and seemed hopeless of further relief. The report of the case which was under observation in Professor Gussenbauer's clinic for several years was read before a recent meeting of the Imperial Academy of Sciences at Vienna. Only a small portion of radium was employed, something less than a sixth of a grain of the bromid salt, which is the most powerful in its radio-activity of any of the salts of the metal yet prepared. The malignant growth, it is reported, gradually disappeared, and there has been a very favorable healing of the ugly sore which existed. At the same meeting a case of melanosarcoma, the form of malignant disease universally acknowledged to be the most fatal in its effects, was reported as having been cured by the same means. The physician in charge considered the prognosis of the affection so hopeless under the ordinary methods of treatment that he preferred to try the effect of the radium rays before having recourse even to simple surgical removal. The tumor completely disappeared, and there is good reason to think that the patient will escape the serious danger which always accompanies this form of malignant neoplasm, no matter how small it may be when first recognized. While authentic detailed reports of the above cases have not been received, the wonderful qualities of radium already recognized make one

1. THE JOURNAL A. M. A., xxxix, p. 846.

ready to accept the statements as facts. The great objection to the general use of the remedy is its scarcity and costliness, but, as above shown, a very minute quantity only is required. This new substance may yet play a very important part in our remedial armamentarium.

THE SPECIFIC TREATMENT OF HAY FEVER.

The recent work by Dunbar[1] on the cause and specific treatment of hay fever is bound to excite great interest among medical men. Dunbar seems to successfully show that the pollen of a great variety of cereals and grasses—rye, oats, wheat, corn, grasses—contain substances that in susceptible individuals, but only in the susceptible, produce the well-known phenomena of hay fever. And these pollens produce hay fever, no matter how or where or when introduced. The active substance is soluble in tears, saliva, nasal secretion and blood serum. Even the hypodermic injection in susceptible persons of the starch rodlets in the pollens mentioned has caused severe conjunctivitis, coryza, cough and asthmatic seizures. These results would seem to settle the cause of hay fever, although the nature of susceptibility or unsusceptibility remains as yet wholly obscure. Dunbar, then, undertook the production of a curative serum by following the principles of immunization. Animals were injected with pollen toxin and after prolonged injections an antitoxin developed in the serum. This antibody not only rendered pollen harmless when mixed with it in the test tube, but it also neutralized the effects of the pollen when introduced into the eye or nose shortly after the local application of the pollen.

So far this neutralization has been successfully done only in the early stages of the process, but the results certainly warrant the hope that a serum may be produced which shall have more extended therapeutic value. Apparently the pollen toxin in the different grasses is the same because one pollen may be neutralized by the antitoxin obtained from the injections of pollen of a different source. This work of Dunbar's is entitled to the confidence of physicians because of the standing of the author, an American who has risen to scientific eminence and the high position of director of the Hygienic Institute at Hamburg, and also because of the evident scientific and thorough character of the work itself, which has extended over a period of seven years. Further reports will be awaited with interest.

SUNSTROKE AND HEAT EXHAUSTION.

The two conditions of sunstroke and heat exhaustion, though occurring from similar or identical causes, are not the same. In heat exhaustion the temperature is only slightly elevated, and may be subnormal, while in sunstroke it is usually well above 103 degrees. Correspondingly, the skin is comparatively relaxed and cool in heat exhaustion, while it is hot and flushed in sunstroke. Unconsciousness and convulsions are rare in heat exhaustion, but are common in sunstroke. Corresponding to the condition of the temperature, the pulse in heat exhaustion is rapid, feeble and perhaps almost imperceptible, but in sunstroke, although it is rapid, and may be feeble, it may also be full. The pulse, therefore, can not in all cases give much assistance. If further evidence is necessary to establish a diagnosis, there may be the history of the patient having complained, in heat exhaustion, of suffering from intense heat, or if he is conscious—as is usually the case—he may himself describe his previous feelings. On the other hand, in sunstroke, the attack in most cases comes on suddenly, and the patient is apparently stricken down while suffering no inconvenience. When diagnosis is made the treatment, it is easily seen, differs in the following: In heat exhaustion the subnormal temperature must be raised to normal; in sunstroke the hyperpyrexia must be reduced. The patient suffering from heat exhaustion must be protected from drafts, have external heat applied and stimulants given. In sunstroke, the stronger and colder the draft, the better. The patient should be rubbed with ice, be given cold water enemas or ice packs, and other measures should be used to reduce the temperature. In sunstroke stimulants should never be given while the temperature remains high and the period of depression following the reaction has not arrived. In case of either affection the patient must be warned to resume work moderately, and only after sufficient time for convalescence. He must be further warned that he will be more liable to such attacks in the future. The pathology of the resulting condition has often been discussed, but whatever the exact injury may be, there often seems to be an irreparable lesion.

A BETTER CONDITION OF MEDICAL AFFAIRS IN HOT SPRINGS, ARKANSAS.

By an act of the Arkansas legislature last winter the jurisdiction of Hot Springs Reservation was ceded by the State of Arkansas to the United States government. One result of this is that the regulation of the practice of medicine comes under the jurisdiction of the national government. The Secretary of the Interior has promulgated a new series of rules for conducting the Hot Springs, including provisions requiring all physicians prescribing and using the hot water to be registered, and a board of physicians has been appointed to pass on their qualifications. This is independent of the Arkansas State medical practice act. The practice of public touting for certain doctors which has been so much the custom in the past is to be abolished. The payment of any sum of money or anything of value by any bathhouse keeper, manager, clerk or attendant as a compensation for drumming customers or such practice by drumming doctors is forbidden. On violation of the rule water may be shut off, or the lease canceled, as the authorities may decide. Any solicitation of patronage by registered physicians will be ground for the cancelment or revocation of their licenses. In times past Hot Springs has been a sort of reproach to the medical profession by reason of the practices there in vogue, and it would seem that now under these new auspices this reproach is likely to be removed. Reputable and qualified physicians will find no difficulty in obtaining the United States license, and disreputable ones will have to take their field of activity somewhere else. It is to be hoped that they will find few places where they can establish themselves. It is said that up to quite recently some of the local physicians there have

been acting as if these rules did not affect them. They have hardly yet had time to be thoroughly effective, but we think the individuals alluded to will find that they have been playing with fire. It may be that the new rules will be attacked in the courts, but we have little fear of the outcome. The United States laws and regulations are usually fairly well supported by the United States Courts, and there are no precedents, so far as we know, especially in favor of the kind of quacks that have existed at Hot Springs in the past, or which would imply that they would receive any practical legal favor in the future. The reputable members of the medical profession at Hot Springs are rejoicing at the change.

Medical News.

CALIFORNIA.

Bard Hospital Incorporated.—The Elizabeth Bard Memorial Hospital, Ventura, has been incorporated with a capital stock of $40,000.

The Last of the Epidemic.—The sixteenth death in the epidemic of typhoid fever at Leland Stanford University, Palo Alto, occurred June 17, and the hospital, which had been in use for two months, is now closed.

One More Plague Case.—The ninety-fifth officially recorded case of bubonic plague at San Francisco was reported June 5, and the diagnosis confirmed by autopsy on the following day. There had been no case recorded since March 17.

Personal.—Dr. and Mrs. Fisher R. Clarke, Stockton, celebrated their silver wedding anniversary, June 6.——Dr. Francis M. Bruner has been elected chairman of the Santa Ana Board of Health, and Dr. John G. Berneike, health officer.

Graduation.—The University of Southern California, Los Angeles, graduated a class of 25 from its medical department June 11. The bishop of Los Angeles, Rt. Rev. Joseph H. Johnson, delivered the address of the evening, and the president of the university conferred the degrees.

GEORGIA.

Medical Scholarships Awarded.—The governor has named four men from the state at large and two from each congressional district as beneficiary students of the Medical College of Georgia, Augusta.

Personal.—Dr. W. Sterling Wilkinson, Augusta, is said to have completed a fast of 53 days, June 28, whereby he cured a dyspepsia of many years' standing.——Dr. Herring Winship has been appointed junior surgeon at the Macon Hospital.

Addition to Faculty.—Seven lectureships have recently been established at the Medical College of Georgia, Augusta, which have been assigned as follows: Dr. William H. Goodrich, genito-urinary diseases; Dr. W. Clifton Lyle, forensic medicine and hygiene; Dr. William Z. Holliday, diseases of children; Dr. W. C. Kellogg, diseases of the skin; Dr. W. R. Houston, nervous diseases; Dr. Andrew J. Kilpatrick, minor surgery and bandaging, and Dr. Henry M. Michel, orthopedic surgery.

ILLINOIS.

New Building for State Hospital.—The contract has been let for a new building at the Illinois Western Hospital for the Insane, Watertown, to be constructed at a cost of $101,900. The new building will add 400 to the capacity of the institution, making a total capacity of 1,200.

Physician Gives Estate to College.—By the will of Dr. Hiram K. Jones, whose death occurred June 16, his entire estate, valued at about $75,000, with the exception of a few legacies to be paid therefrom, was bequeathed to Illinois College, Jacksonville, with which he was connected for many years.

Personal.—Dr. Carey Culbertson and wife, Piper City, prior to their departure for Europe, were given a reception, at which a handsome steamer rug was presented to them. Their objective point is Vienna.——Dr. Lewis C. Taylor, Springfield, has been appointed assistant surgeon-general, with the rank of lieutenant colonel, and has been assigned to the newly-organized Fourth Brigade.

Warning.—A correspondent in Lewistown, Fulton County, warns against Dr. A. A. Potter, an advertising itinerant, who has been making much money from the people of that section by advertising to cure all diseases free. He was fined $100 and costs for violation of the medical practice act, but escaped without payment of the fine. The sheriff of Fulton County would be glad to receive information as to the whereabouts of this individual.

Chicago.

Hot Weather Kills.—The week ended July 4 showed the result of the sudden onset of hot weather, as 563 deaths were recorded, an increase of 109 over the preceding week, or about 24 per cent.

Hospitals To Be Given Permits.—The corporation counsel has advised Health Commissioner Reynolds to issue licenses to general hospitals, even though neighboring property owners should object, serve written notice on the mayor and commissioner, and threaten suit for damages.

Pure Milk Plant Opened.—The milk-pasteurizing plant of the Children's Hospital Society, established through the munificence of Mr. and Mrs. Nathan Strauss of New York City, was opened for the summer on July 1. The milk will be supplied at less than cost, from sixteen substations situated in the more congested centers of population of the city.

Commencements.—Jenner Medical College held its graduating exercises June 30. Dr. G. Frank Lydston delivered the doctorate address on "The Young Man's Way to Success."—— Harvey Medical College graduated a class of 20 on June 27. Dr. Frederick D. Marshall presided and Carl Svante Nicanor Hallberg, Ph.G., on whom was conferred the honorary degree of Doctor of Medicine, delivered an address.

Reduced Mortality.—The forecast of the Department of Health of May 23 has been fully verified, as shown by the following figures of successive weekly death rates since that date: May 30, 16.12; June 6, 12.73; 13th, 13.06; 20th, 12.48; 27th, 12.54. For the month of June the total 2,042 recorded deaths represent an annual mortality of 13.16 per 1,000—a decrease of more than one-fifth (21.1 per cent.) from the May, 1903, rate and of 6.8 per cent. from the average June rate of the previons ten years.

Alumni Week at Northwestern.—The exercises of alumni week at Northwestern University Medical School were attended by about 200 former graduates of the institution. Special clinics were held during the week, and for the banquet which had been planned in the Auditorium Hotel, an al fresco lunch with student waiters in the Physiological Laboratory was substituted on account of the strike of the waiters. Dr. Archibald Church was toastmaster, President James of the University welcomed the guests, and Hon. A. N. Waterman, Rev. I. A. White and Frederick Greeley spoke.

IOWA.

Revenue from Itinerants.—It is reported that the state of Iowa will receive in 1903 a revenue of nearly $20,000 from medicine pedlers at $100 a license.

Back from Europe.—Dr. Will L. Hearst, Cedar Falls, has returned after a year's absence in Europe.——Dr. Aram G. Hejinian and family of Anamosa have returned after a stay of eight months in Europe.

Hospital Opened.—The formal dedication and opening of Mercy Hospital, Council Bluffs, took place June 11. The hospital has cost about $75,000, and contains 113 rooms. In its appointments and equipment it is said to be unequaled in the state.

University Changes.—The following changes in the teaching staff of the College of Medicine of the University of Iowa are announced: Dr. Lawrence W. Littig, professor of theory and practice of medicine and clinical medicine, has resigned, and Dr. Walter L. Bierring has been elected to that chair; Dr. Henry Albert has been elected assistant professor of pathology and bacteriology.

Personal.—Dr. James G. McAlpin, Grundy Center, started for Europe July 1. He expects to study in Vienna, Paris and Edinburgh for a year.—— Dr. Charles B. Adams, Sac City, has been elected president of the State Board of Medical Examiners, vice Dr. John A. McKlveen, Chariton.—Dr. John W. Harriman has been elected president of the staff of the University of Iowa Hospital, Iowa City, and Dr. Lee W. Dean, secretary.

Endow Medical Journal.—The only endowed journal in the world devoted to the study of infectious diseases is to be published in Chicago. Commencing in the fall *The Journal of*

Infectious Diseases, edited by Dr. Ludvig Hektoen and Prof. Edward O. Jordan of the University of Chicago, will be issued. The expenses of the publication, which, it is estimated, will amount to $5,000 annually, will be met by Mr. and Mrs. Harold McCormick. This agreement is made for an indefinite term, and amounts practically to a $125,000 endowment.

KENTUCKY.

Damage Suit.—Dr. Cuthbert Thompson, Anchorage, recently received a verdict in his favor in a suit against him for $10,000. The suit was brought by a woman 76 years of age who had sustained a Colles fracture of the left forearm twenty-two months before.

Pioneer Physician Ill.—Dr. James M. Holloway, Louisville, is seriously ill as a result of a fall two weeks ago. It was at first thought that his skull was fractured, but it afterward proved that he had concussion of the brain. His advanced age, of course, makes his condition more serious.

Medical College Incorporated.—The Kentucky University Medical Department was recently incorporated with a capital stock of $45,000, by Drs. Joseph B. Marvin, Thomas C. Evans, James M. Holloway, J. Garland Sherrill, Samuel E. Woody, Henry E. Tuley, Louis Frank, Leon L. Solomon, and W. Ed Grant.

To Make Entrance Examinations More Rigid.—The Kentucky State Board of Health, at its June 10 meeting, passed the following preamble and resolutions:

WHEREAS, In violation of published requirements, many low-grade schools offer private inducements to medical students for admission, reduced time of attendance on lectures, scholarships and reduction of fees, to induce them to enter on the study of medicine to their own disadvantage, and contrary to the interests of humanity; be it

Resolved, That the State Board of Health of Kentucky will not recognize as reputable any medical college which violates its published requirements for admission, tuition and the time of attendance at the annual sessions, which requirements must be definitely expressed. The college shall require of each applicant for matriculation evidence of good moral character and a certain showing that he is a graduate of a recognized normal school, high school, academy or college of literature, science or arts, or a certificate from a county superintendent of public instruction showing that he has passed a satisfactory examination in the following branches: In English, composition, submitting a composition on some subject of general interest embracing not less than two hundred words, which shall be considered with reference to spelling, punctuation, thought and construction; in arithmetic, showing knowledge of decimal fractions, percentage and compound numbers; in algebra, simple equations; in Latin, first year of one ordinary Latin course; in physics, the elements of mechanics, hydrostatics, hydraulics, heat, optics and acoustics; or, in default of such certificate, he shall be examined in the above-named subjects by the superintendent of schools in the city in which the college is located and obtain and present his certificate.

No college shall offer or accept scholarships, or any reduction in fees, except as provided for and required under state laws, or under the laws of endowed universities.

No note accepted by any college in payment or part payment of fees, or any form of rebates will be recognized as complying with the above requirements, and no student shall be given credit for attendance on lectures, or for examination for advanced standing until all fees shall have been paid, nor shall the degree be conferred on anyone under other conditions.

Each student must have been in actual attendance for the full term in each of the four years required in the curriculum.

Each applicant graduating on and after July 15, 1903, shall make affidavit of compliance with the above requirements for each and every year after July 15, 1903.

MARYLAND.

Hot Weather Deaths.—The hot weather in Baltimore sent the deaths last week up to 262, 50 being of children under 5. The annual proportion was 24.68 per 1,000.

Medical Journal Declares Dividend.—The shareholders of the Maryland Medical Journal Company of Baltimore and Washington, at its annual meeting, June 19, declared a dividend and re-elected the old board of directors.

Bequests to Hospitals.—Minka Friedmann left by his will $500 to the Hebrew Hospital, and John Uhrig left $100 to the same institution.——Katharine Gibson by will left $1,000 to the University of Maryland Hospital toward the endowment of a bed in that institution.

Personal.—Dr. James A. Stevens, Oxford, has been elected state medical examiner by the Medical and Chirurgical Faculty of Maryland, vice Dr. Charles F. Davidson, Easton, who declined re-election.——Drs. A. D. McConachie, Frank D. Sanger and John Ruhräh, Baltimore, have sailed for Europe.——Dr. J. C. King, Salt Lake City, Utah, sailed from Baltimore for Bremen July 1, and Dr. W. J. Craigen, Cumberland, for Jamaica, on the same date.——Dr. William T. Howard has gone to the White Sulphur Springs, Va., for August, and will spend September at Narragansett Pier.

MICHIGAN.

Reported Epidemics.—Typhoid fever is reported to be epidemic at Escanaba, and diphtheria at Benton Harbor.

Michigan Falls in Line.—Michigan has adopted the American Medical Association resolutions concerning the examination of the eyes and ears of school children.

Accident to Physician.—Dr. Frank A. Grawn, Munising, while returning home after having made a call, was thrown from his bicycle into a barbed-wire fence, sustaining serious cuts and bruises.

Personal.—Dr. Allen D. McLean, Detroit, has passed the examination for the medical department of the U. S. Navy.——Dr. Jabez Perkins, Owosso, who has been a practitioner for more than half a century, was made an honorary member of the Michigan State Medical Society at its recent meeting.——Dr. Arthur D. Holmes, Detroit, for eleven years lecturer on pediatrics in the Michigan College of Medicine, has resigned.——Dr. Theodore F. Heavenrich, Detroit, has been elected medical director of the Port Huron Hospital and Home Association to succeed Dr. Hiram R. Mills, who has moved to Grand Rapids.——Dr. Elliott K. Herdman has been elected city physician of Ann Arbor.

Would Educate the People.—At the meeting of the State Board of Health, June 10, the following resolution was unanimously adopted:

Resolved, That the state board of health shall each year publish and transmit to boards of supervisors and local boards of health throughout the state the scientific and common names of diseases dangerous to the public health. Such lists shall contain the names of dangerous communicable diseases already existing in the state, or which, in the opinion of the state board of health, are liable to be present during the year following each publication. Diseases communicable from animals to man shall also be included in these lists. Accompanying the lists shall be brief statements of how each of the dangerous diseases is spread, and the proper steps to be taken for its restriction by local health boards and health officers at every outbreak of such disease.

MINNESOTA.

Newly Licensed.—Licenses were issued by the State Board of Medical Examiners, June 19, to 108 applicants who had successfully passed the examination.

Minnesota in Line.—The Minnesota State Medical Society has adopted the resolutions of the American Medical Association anent the examination of the eyes and ears of school children.

Smallpox Waxes.—The smallpox report of the State Board of Health for the week ended June 15 shows 143 new cases in the state, 55 of which were in Renville County. Only one death was reported.

Advisory Board for Consumption Sanatorium.—Governor Van Sant has appointed the following advisory board for the sanatorium for tuberculosis to be located near Walker: Drs. George B. Weiser, New Ulm; Alonzo P. Williamson, Minneapolis; James L. Camp, Brainerd; George S. Wattam, Warren, and H. Longstreet Taylor, St. Paul.

Commencements.—The College of Medicine and Surgery of the University of Minnesota graduated a class of 73 June 2. Dr. John M. Dodson, dean of the medical department of the University of Chicago, delivered the annual address on "The Relation of the University to Professional Schools, Medical and Otherwise."——The medical department of Hamline University held its graduating exercises June 1. A class of 34 received degrees, and Rev. Irving R. Johnson delivered the doctorate address.

MISSOURI.

Medical College Expands.—Barnes Medical College, St. Louis, has established pharmaceutical and dental departments.

Leaves Large Estate.—The will of the late Dr. Andrew L. Chapman, Kansas City, devises an estate valued at $260,000.

Resolutions Regarding Dr. Bryson.—The St. Louis Medical Society of Missouri, at a meeting held soon after the death of Dr. John P. Bryson, adopted resolutions eulogizing the character and attainments of its deceased member, and detailing his work as a physician, teacher and writer.

Hospital Appointments.—The health commissioner of St. Louis has appointed Dr. William J. Doyle assistant to the superintendent of the City Hospital, and Dr. C. P. Glahn senior assistant.——Dr. H. J. Sherk has been appointed chief dispensary physician by Health Commissioner Simon of St. Louis.

Many Graduate.—Barnes Medical College, St. Louis, graduated a class of 100; Marion-Sims-Beaumont Medical College, 96, and the St. Louis College of Physicians and Surgeons, 59;

University Medical College, Kansas City, conferred degrees on a class of 63, and Kansas City Medical College graduated a class of 24.

NEW YORK.

New York City.

Physician Beaten and Robbed.—Dr. Benjamin Hawker, a retired physician, was assaulted and badly beaten by two burglars in his house, 141 East 52d street.

Illegal Practitioner Fined.—Charles Sampsell, practicing as "Dr. E. D. Porter," was recently arrested on the charge of practicing medicine without a license, and was fined $50.

Personal.—Dr. William T. Bull sailed for Europe, June 27. ——Dr. Frank Hinkley, Brooklyn, has been appointed junior physician at the Manhattan State Hospital.——Dr. Luther Halsey Gulick, the director of physical training in the public schools of this city, has been elected president of the American Physical Education Association.

Charity Curtailed.—The well-known work of the floating hospital of St. John's Guild must be curtailed this summer because of lack of funds. The first trip of the floating hospital was made on July 7, but the service to Brooklyn will be entirely discontinued this year, and there will be an alternate service to the east and west sides of New York only.

Steals Doctor's Horse.—A blacksmith went to the stable where Dr. Guilford Allen keeps his horse, and succeeded in getting permission to take the animal out on the plea that he had been sent by the doctor to exercise it. He then took the horse to several stables, trying to effect a sale. He was arrested by a police captain while thus engaged.

Epidemics on Staten Island.—Measles and whooping cough are raging on Staten Island, or Richmond Borough. In one public school at Westerleigh as many as 75 per cent. of the pupils were ill with measles. The epidemic of whooping cough began at Tottenville about two weeks ago, and is spreading with such great rapidity that it is already to be found in almost every family in that place.

Woman an Ambulance Surgeon.—Considerable popular interest has been aroused by the fact that New York's first woman ambulance surgeon has begun active service. For the past six months Dr. Emily Dunning, a New Yorker, has been busy as a junior surgeon in the accident ward of Gouverneur Hospital, and on July 1 her service as ambulance surgeon began. With the exception of a "rainy day" skirt and the regulation ambulance surgeon cap she dresses as do other women, and seems to experience no special difficulty in attending to the arduous duties of her office.

Health Board and Sick Babies.—The health department announces its intention of inaugurating at once a crusade among the 50,000 babies born in the city in the past year. A corps of 43 physicians and 17 nurses will engage in this work, to facilitate which the city has been divided into 160 districts. The mothers are to be taught how to care for and feed their babies, and the nurses will assist in carrying out the directions of the physicians. No doubt the work will be pushed vigorously, but it seems hard to credit the published statement that this fostering is to be given indiscriminately to both rich and poor.

GENERAL.

No Room for Kokuas.—The Honolulu Board of Health at its meeting, June 17, decided that, on account of the crowded condition of the Lunalilo Home, it would be impossible to admit Kokuas from Molokai to that institution.

First American Plague Victim.—Mr. Frank Twombley, an American contractor of Manila, died on April 24 from bubonic plague. The diagnosis was confirmed by Major Edward Champe Carter, surgeon, U. S. Army, Commissioner of Public Health.

No Physicians for Postoffices.—Postmaster General Payne issued on order abolishing the position of physician in postoffices at the close of business June 30. The postoffices employing physicians are New York, Chicago, Brooklyn, Philadelphia, and Boston.

Jaro Hospital Completed.—Advices from Iloilo, P. I., under date of May 20, state that at that time the new hospital at Jaro was almost completed, and that several wards were already occupied. Drs. H. E. Winslow and L F. Raymond are in charge.

Physicians in Porto Rico.—In a letter from Dr. Wm. Fawcett Smith, secretary of the Superior Board of Health of Porto Rico, he says that it will be a kindness to prevent any physician from coming to Porto Rico under the existing conditions, and suggests that the publication of this notice may save serious loss and disappointment to physicians who had intended to settle in the island.

A Warning and a Request.—The Medicolegal Department of the Chicago Medical Society desires us to announce that a man who claims to be Dr. Theo. Jennings robbed the office of Dr. Dickey of Toledo, Ohio, last week. On Saturday evening Dr. Byron Robinson of Chicago cashed a check for him to which he had forged the name of Dr. Dickey. He is probably addicted to cocain. He is about five feet eight inches in height, about forty years old, is disheveled in appearance and very nervous in manner. Any physician knowing anything about him is asked to notify the Chicago detective department, or Dr. W. A. Evans, 103 State Street, Chicago.

Dr. Howard A. Kelly Abroad.—Dr. Kelly seems to be making an impression abroad judging by the notices in our exchanges. We quote from the *British Medical Journal* in regard to his visit to Glasgow: "The arrangements for the visit of Dr. Howard A. Kelly to Glasgow last week were carried through with great success. Dr. Kelly had been elected honorary president of the Glasgow Obstetrical and Gynecological Society, and in the Faculty Hall on the evening of June 17 he delivered his presidential address before a crowded audience of professional men and women. The subject was 'The History of Appendicitis in Great Britain,' and Dr. Kelly traced the development of our knowledge of appendicitis as a separate disease and its surgical treatment from the beginning of the nineteenth century, pointing out the important part Britain had played in that development. The address was interesting and racy, and was evidently meant as a compliment to British physicians and surgeons. Needless to say, it was enthusiastically received. On the afternoon of June 18 there was a combined meeting of the Glasgow and Edinburgh Obstetrical Societies, when a discussion took place on Extirpation of the Uterus and Its Appendages in Serious Pelvic Inflammation, Dr. Kelly introducing the discussion. In the evening of the same day Dr. Kelly was entertained at dinner in the Windsor Hotel. The president of the Glasgow society, Dr. Nigel Stark, occupied the chair and there was a large gathering, which included the leading members of the profession in both Glasgow and Edinburgh. In proposing 'The Health of Dr. Howard Kelly' the chairman paid a high tribute to his distinguished services to surgery, eulogizing the improvements he had inaugurated which had made his name famous all over the world. Dr. Kelly, in reply, thanked the Glasgow society for the great honor it had paid him by electing him its honorary president, and dwelt on the cordiality of the relationship that exists between Britain and the United States."

Referring to the address he delivered in French at Paris, before the Société de Chirurgie, the *Gazette Méd. de Paris* remarks: "Professor Kelly operates in the most splendid hospital in the world, in a marvelous university, and he possesses a private library almost as rich as that of the Institut de Bibliographie at Paris, while he is devoted to bibliography. His coming to Paris to address his French confrères in their own tongue on the Rôle of France in the History of Appendicitis, is a tour de force that very few members of the French society could return in kind, for very few know English, and still fewer are posted in regard to American bibliography."

The editorial concludes: "Certes, c'est là de la coquetterie, but it is piquant to see an American, the type of the active, practical man, disport among the old dusty tomes of the eighteenth century and the forgotten files of the first scientific periodicals, as much at home as a Roosevelt on the tops of the Rocky Mountains! There is no doubt about it, the future belongs to the United States. The Latins are dead, and Panama will give them the finishing stroke."

FOREIGN.

La Syphilis.—A new monthly has been founded at Paris with the above descriptive title. Dr. T. Barthélemy, 22 rue de Notre-Dame-de-Lorette, is to have editorial charge.

Sanatorium for the Madeira Islands.—The *Riforma Medica* states that Prince Carl von Hohenlohe has applied to the Portuguese government for permission to erect two extensive sanatoria on the Madeira islands. He agrees to construct two and have them ready in two years, one for the wealthy and one for the poor.

Sequel of the Larceny Case Against a Paris Physician.—Sentence has been suspended in the case of the young Paris physician who was condemned to six months' imprisonment on account of petty larceny to keep himself from starving. A

small town in the interior needed a physician, and he has removed there on the recommendation of other physicians, who know that he had done good work, as his thesis testified.

A Second Victim of the Laboratory Plague at Berlin.—All the persons who attended Dr. Milan Sachs during his illness were treated with preventive injections of antiplague serum, but one of them developed the disease. Possibly on account of the preventive injections, it had a very mild course and recovery was soon complete. The entire furnishings of the apartment where Dr. Sachs had lodged were taken to the disinfecting headquarters and burnt.

The Correspondent of the Paris "Semaine Medicale" Caught in the Kansas Floods.—In passing through Kansas City, June 3, Dr. Münch was stopped by the floods and was obliged to abandon his baggage containing all his memoranda and escape to the bluffs, as he writes. His letters are, therefore, suspended for the present. They have proved an interesting series of sketches, showing that we really gain in our own estimation when we see ourselves in certain respects as others see us.

Honors to the Late Professor Bottini.—The friends and pupils of the recently deceased Professor E. Bottini had planned a Festschrift in his honor with a gold medal and souvenir copy of his diploma on the occasion of his jubilee anniversary. The anniversary came soon after his death, and the University of Pavia was made the recipient of the honors in his name, the medal, diploma and Festschrift to be duly preserved among the archives of the institution with the list of subscribers.

Autoinoculation with Bovine Tuberculosis by Dr. Garnault of Paris.—Dr. Garnault's experiments on himself to refute Koch's assertions in regard to the non-identity of human and bovine tuberculosis, have resulted negatively, as we have previously reported. No general infection has followed and the local tubercles on the arm soon healed. No tubercle bacilli nor caseous tissue were found in them. Garnault is an athlete and possibly the experiments might have resulted differently on a less perfect physique, but as it is, our German exchanges either ignore his experience altogether or refer to it as resulting in a confirmation of Koch's statements, instead of a refutation.

Ankylostomiasis in the Westphalia Mines.—The *Allg. Med. Ct. Ztg.* states that it is reported from Bochum that a new source of infection has been recently discovered there. The parasites were found in large numbers in the eggs of hens which had access to fields fertilized with miners' dejecta. All the members of the scavenger's family, who were in the habit of eating eggs raw, were found to have the disease. The hens showed no symptoms of it, but investigation of the eggs revealed the larvæ in profusion. Our exchange adds that the case requires scientific confirmation, but states that according to the latest figures there are fully 25,000 cases of the disease in the Westphalia mines.

Death of Professor Gussenbauer.—Dr. Karl Gussenbauer, the eminent surgeon of Vienna, "Hofrath" and president of the University, died June 19, aged 61, after a brief illness due to a heart affection. He was the son of a country physician at Ober Vellach and was assistant to Billroth after graduating from the Vienna medical school. He became docent in 1874, and the year after was called to Liège as professor of surgery, and two years later to Prague, whence he was summoned to Vienna in 1894 as the successor to Billroth. The week before his death he went to Vöslau, accompanied by the dean of the medical faculty, to present the renewed medical diploma after fifty years to Professor Drasche on his silver jubilee.

Leprosy in the Danish West Indies.—Professor Ehlers was commissioned by the Danish government to study the conditions in regard to leprosy in the three Danish West Indies, St. Thomas, St. Croix and St. Jean. He has just handed in his report, which states that he found 102 cases of leprosy on the islands, and that the number is less than formerly. At the same time he proclaims that there are no adequate provisions, and that more stringent regulations are necessary to prevent immigration of lepers. He also pleads for the erection of a suitable leper asylum. He found the disease of a milder character than in more northern countries and states his opinion that this form is curable by proper treatment and care.

Declining Death Rate in Europe.—The German Bulletin of Vital Statistics states that the death rate in the German Empire has fallen from 26.8 per 1,000 during the decade 1841-1850, to 22.2 in the last decade. For comparison it gives the death rate for the same decades in other European countries: In Austria it has fallen from 32.8 to 26.6; France, 23.3 to 21.5; England and Wales, 22.4 to 18.2; Belgium, 24.4 to 19.1; Denmark, 20.4 to 17.4; Sweden, 20.6 to 16.3, and in Norway from 18.2 to 16.2. During the last decade the death rate in Switzerland was 19.4; in Italy, 24.7; in Hungary, 29.7 and in European Russia, 33.5. The *Deutsche Med. Wochft.* comments that the death rate is, therefore, highest in Hungary and Russia, but the birth rate in these countries is exceptionally high.

The Bufalini Prize.—The R. Istituto di Studj superiori at Florence, Italy, notifies us that the Bufalini prize of $1,200 is open to competition again. It is awarded every twentieth year, and all competing articles must be received by the chancellor of the medical department, Via degli Alfani, 33, before the end of October, 1904. They must be sealed and written in Italian. The theme is the value of the experimental method in opposition to the speculative or dogmatic method of scientific research. The first part of the article should deal with the subject at large, and in the second part the author must review the way in which the single sciences have followed this method during the last twenty years, and how they can be induced to a more faithful and complete observation of its principles. The prize may be divided, and the writer may limit his article to one of the parts alone.

Longest Survival in Accidents.—The Tarbé case is attracting much interest at Paris. This wealthy couple were found asphyxiated by carbonic oxid one morning from a defective flue. Brouardel and Ogier testified as medicolegal experts that it was impossible for them to determine positively which of the victims had succumbed first, but that the probabilities were in favor of the assumption that the husband had survived longest, as his cadaver was not so pale nor so cold as that of the wife. The spectators unanimously applied their efforts to resuscitate him, leaving the wife as past all aid. Lacassagne of Lyons, on the other hand, affirms that the medical presumption is in favor of the survival of the wife, citing among other reasons that the carbonic oxid might have been able to maintain the warmth and the coloring in the cadaver most profoundly intoxicated. The decision of the court has not yet been rendered.

The Question of Languages at International Congresses.—Professor Küster of Marburg is indignant because some of his compatriots at the Madrid Congress delivered their addresses in French or some other language, thus belying their national tongue. Professor Holländer of Berlin takes issue with him and thinks that some concession is necessary or the orator will find himself talking to empty benches, to say nothing of the courtesy of conciliating the members of other nationalities. He suggests in a letter to the *Deutsche Med. Wochft.*, as perhaps the best plan, that the communications should be made in the mother tongue of the speaker, followed by a brief summary in the language of the country where the congress is held. If this were adopted as a regular measure, he believes that it would prevent the choice of meeting places where Portuguese or a similar little known language is spoken. He remarks in parenthesis that as China and Japan have drawn their science so extensively from Germany, the German language would be understood at a scientific gathering there, and might thus be considered the home tongue of the national members.

Deaths Abroad.—Dr. R. Juergens, custodian of the Pathologic Institute at Berlin, died June 14, aged 60. For thirty years he was Virchow's trusted assistant and had received the titles of docent and professor, his work being principally in the line of the post-graduate or vacation courses. His contributions to pathologic anatomy are numerous, among them a new reaction for amyloid degeneration.——The death is also reported of Dr. Karl Gegenbauer, formerly professor of anatomy at Heidelberg. His seventieth birthday was celebrated with much ceremony by his friends seven years ago, when his works on comparative anatomy were scheduled in full. ——From Paris is announced the death of Dr. Gerard Marchant, following close upon that of Dreyfus-Brisac and of Boilly, all eminent surgeons in the prime of life. Marchant was born at Toulouse in 1850 of a medical family; during his interne service he suffered from diphtheria, and later from appendicitis, one leaving paralysis for a year and the other requiring months of convalescence. The surgical service at the Boucicault hospital in his charge was a model in every respect, and from it have issued numerous memoirs on surgical subjects from his pen or those of his pupils. His latest works were on "Recto-coccy-pexie" and "Hépato-pexie."

Warning Against Quacks in Germany.—The authorities of Berlin and its province are publishing the following cir-

cular of warning for the public, drawn up by a committee appointed by the Berlin Medical Chamber: "While physicians thoroughly trained and approved by the state disdain to advertise their services, there are numbers of other persons who have no training or special knowledge who yet seek to delude the suffering public by advertising in the papers, or distributing circulars or by worthless books in the hands of agents, assuming false titles, making baseless promises and publishing forged or bought or fraudulent testimonials. The immense sums paid out for this advertising demonstrate the large profits that are made out of this business. During the eight years ending 1897 there were 177 criminal suits against these charlatans on account of severe injury or death from their practices, and the total resulting imprisonment amounted to 63 years, 3 months and one day. The legislature assumes that the public is enlightened enough to protect itself against such swindling speculation on the credulity of the sick. The public should apply the ordinary prudence customary in business transactions to matters affecting health and even life itself! The title of physician alone guarantees that the bearer has been found fully qualified by the state. All other titles should be regarded with mistrust. All published testimonials should likewise be mistrusted unless the person signing the testimonial is personally known and personal inquiry has been made."

Organization of the Rising Generation of Medical Men in Austria.—The medical profession in Austria is not well organized and the attempt to hold a general meeting this spring to discuss economic questions failed principally on account of race jealousies and prejudices. The rising generation, however, appreciates the necessity for organization and the benefits that may accrue from it. The medical students and internes throughout Hungary and Austria had certain grievances and wished for improved facilities and opportunities. After due deliberation they held a large representative and harmonious meeting at Vienna, June 7 to 10, which was marked by moderation and business-like methods. A number of physicians and professors took part in the proceedings, and the president of the Vienna Medical Chamber, Dr. Heim, remarked in greeting the congress, that the fact that the medical students had aimed at comprehensive organization had caused the medical profession at large great satisfaction and aroused sincere rejoicings and profound sympathy, "but at the same time," he continued, "we can not repress a sentiment of sorrow when we see that the years of student life which used to be so free from care and responsibility, are now filled with concern to better the material conditions of the coming years. It is a struggle for existence of the bitterest kind for which the medical student is preparing, and it must find young and old firmly united in order that the aims sought may be realized." This "Mediziner-Congress" has evidently made a great impression, both on the authorities and on the general public. The resolutions adopted asked for numerous reforms, some of them still unrealized in any country, but the majority merely correspond to the measures in vogue in other lands. The minister of public instruction in an unofficial interview stated that he would appoint a committee of experts to consider the resolutions when they were formally presented, and would strive in every way to comply with the demands of the congress.

Campaign Against Charlatans in Germany.—The German imperial government has notified the various state authorities that more energetic measures must be taken against quacks. The official circular states that the number of charlatans has enormously increased during the last decades, and quack practices have assumed such proportions as to become a serious menace to the public welfare, equally detrimental to the interests of the public and to those of the medical profession. The circular reviews the various measures that have been enforced in Prussia, registration of unqualified, so-called healers, the prohibition of extravagant promises to cure and prosecution of charlatans for illegal practices, and remarks that these measures have not proved an effectual check. Consequently, it is proposed, in the interests of the public, to confer further powers on the local authorities to enable them to put an end to such practices in future, at least in the cases in which the charlatans have already done injury to the life or health of the patients who have applied to them, and in those cases in which from the antecedents of the charlatan or his personality, attempts to fleece the public may be feared. In such cases the local authorities are empowered to prohibit the quack from practicing further. The law against fraud in business is to be extended to cover illegal practice of the healing art. The official circular is quoted in full in all our German exchanges as an important advance in the campaign against charlatans which the medical profession has been waging. A cable report states that these professed curers will be given a month to secure other employment, after which time they will be prosecuted if they persist in practice. One newspaper correspondent cables that the government is in possession of statistics which show that more than 100,000 men and women are illegally practicing medicine and the art of healing in Germany, and that this number is rapidly increasing. One medical statistician says he has found 150 cases of cancer in his province. Of these 25 are attended by authorized physicians and 108 by quacks. He maintains it is nearly as bad in other diseases which particularly call for trained medical aid. Most of these quacks allege that they have occult powers, personal magnetism, "magnetic eyes and hands," and that a cure will be the immediate consequence of implicit reliance on this treatment. In some of the large cities of Saxony, Dresden, Leipsic and Chemnitz, it is not unusual for an ignorant quack to receive from $1,500 to $2,000 a year, an income beyond the average earnings of the scientifically equipped medical man throughout Germany. Attention is also directed to the number of women quacks who profess to have magnetic powers. In Saxony alone there are several hundred, and among their patients are some of the proudest names in the land.

LONDON LETTER.

The Investigation of Tropical Diseases.

A parliamentary report containing "papers relating to the investigation of malaria and other tropical diseases and the establishment of schools of tropical medicine" has been issued. It opens with a circular dispatch addressed by Mr. Chamberlain, the colonial secretary, to the governors of all British Colonies on May 28, in which the progress of malaria investigation and of the training of medical officers in the treatment and prevention of tropical diseases, is reviewed. Mr. Chamberlain says that the great mortality among Europeans in climates like those of the West African Colonies and Protectorates had attracted his notice from the first, and toward the end of 1897, largely through the interest taken in the matter by Dr. Manson, medical adviser of the Colonial Office, his attention was more definitely drawn to the importance of scientific inquiry into the causes of malaria, and of making provision for educating the medical officers of crown colonies in tropical medicine. In pursuance of the second of these objects it seemed advisable (1) that a special training school in tropical medicine should be established; (2) that the leading British medical schools should be induced to give greater prominence in their schemes of study to tropical medicine; (3) that the periodical medical report sent in from the tropical colonies and protectorates should be recast on one uniform type, designed to throw light on the prevailing tropical diseases. In February 1898, negotiations were opened by the Colonial Office with the Seamen's Hospital Society, with a view to obtaining accommodation for the proposed tropical school in their branch hospital at the Albert Docks. The school was opened, November, 1899, provision being forthwith made for the training of colonial medical officers, either there or in a similar excellently equipped school at Liverpool, which had been established shortly before. So far the school has just paid its way, and much valuable teaching work has been done. But increased accommodation, both for research and residential purposes, is greatly needed, and Mr. Chamberlain anticipates that a sum of $60,000 will be required to cover the cost of the new buildings. In July, 1898, Mr. Chamberlain invited the co-operation of the Royal Society in equipping a scientific investigation on the spot into tropical diseases, particularly in such deadly forms as the malarial and blackwater fevers prevalent on the West African coast. A joint committee was appointed, and the experts selected for the work—Dr. Daniels of British Guiana, Dr. Stephens, and Dr. Christophers of University College, Liverpool—began their investigations. On the West Coast of Africa they studied the distribution and natural history of several species of anopheles. They made the most important discovery (made independently at the same time by Koch) that while the native adults are immune to malaria the disease is prevalent in native children. They showed that the native is a prime agent in the infection of Europeans, and that the segregation of the white man from the native is important. They proceeded to India, where they found that the native children also harbor, but to a less extent, malarial parasites. They showed that the percentage of native children infected may be taken as the index of the prevalence of malaria in the district and that there is a connection between this index and the presence or nearness of the breeding places

of the offending anopheles. Blackwater fever, their observations have led them to conclude, is essentially of malarial origin. Though with the onset of an attack the organisms disappear from the blood they leave distinctive traces in the corpuscles. The occurrence of blackwater fever coincides with high malarial endemicity.

Fatal Tracheal Compression by Enlarged Thyroid in the New-Born.

At the Edinburgh Obstetrical Society Dr. Angus Macdonald described a case of this rare condition. An infant was born at eight months, ten minutes before the accoucheur arrived. He found the child in advanced asphyxia, but after performing artificial respiration the breathing was partly established. The thyroid was enlarged, its lateral lobes being of the size of a marble and of firm consistence. The breathing became more labored, the lower limbs being drawn in with each inspiration, and four hours after birth tracheotomy was performed, but death occurred during the operation. The thyroid was covered with a network of congested veins, and the lobes seemed to swell as the body was more cyanosed. Sir J. Y. Simpson has recorded the case of an infant who died eight hours after birth from pressure of a goiter as large as a hen's egg, which caused a forehead presentation. In 1855 Kieller recorded a case in which a large irregularly lobulated swelling in the region of the thyroid gland gave trouble by causing a forehead presentation. A. R. Simpson recorded in 1866 a case in which an enlarged thyroid caused dyspnea and dysphagia, but at the age or 4 years it was shrunken, and the child appeared healthy. In Dr. Macdonald's case neither parent suffered from thyroid enlargement.

Chorion Epithelioma.

At the Obstetrical Society Dr. Teacher (Glasgow) read an important paper on chorion epithelioma and the occurrence of chorion epitheliomatous and hydatidiform mole-like structures in teratomata. With the aid of drawings and photographs of microscopic preparations he discussed and illustrated the nature and origin of chorion epithelioma and its relations to the placenta, hydatidiform mole and certain tumors which were not related to pregnancy, but showed the same histologic characters. His conclusions were as follows: (1) The so-called deciduoma malignum arises in connection with pregnancy from the chorionic epithelium (or its forerunner the trophoblast) which is of fetal epiblastic origin. (2) These tumors form a characteristic group clinically, pathologically and developmentally, and should be classed neither as sarcomata or carcinomata, but as a distinct group *sui generis*. The most appropriate name is chorion epithelioma. Malignant hydatidiform mole may be treated as a variety of the disease. (3) Tumors containing precisely similar structures as those that develop from pregnancy may occur in other parts than the uterus and in both sexes. Probably they are teratomata arising from some structure with the morphological value of an included ovum and the chorion-epitheliomatous tissues represent the actual trophoblast of the included ovum.

Correspondence.

A Year's Experience in Organization in Michigan.

DETROIT, MICH., June 20, 1903.

To the Editor:—It is characteristic of the American to demand the test of experience ere accepting the dicta of science. Medical sociology affirms certain propositions relative to medical organization, but their acceptance is delayed for lack of experimental proof. As a contribution to this proof is the experience of Michigan during the past year. This experience began with the annual meeting, June, 1902, at Port Huron. Then, as a result of an exhaustive study of the situation, past, present and future, the Michigan State Medical Society unanimously adopted a new constitution and by-laws, in accord with modern methods. Officers were elected to carry out the details of the change. Some of the results may be catalogued thus:

The meeting of 1902 adjourned with a paid-up membership of about five hundred; eleven months later with seventeen hundred and twelve. June, 1902, it had no branches and scarcely half a dozen live county societies; June, 1903, it had fifty-eight branches, including seventy-eight out of eighty-three counties in the entire state; June, 1902, it had a cash balance of six hundred dollars; June, 1903, it had a balance of above one thousand dollars; June, 1902, forces of repulsion dominated the profession in Michigan; June, 1903, forces of attraction were everywhere in ascendancy; June, 1902, the study of scientific methods of organization awoke the hope that the Michigan profession might assume a place of beneficent influence worthy of the great state of which it was a part; June, 1903, found every member proud of past achievement in a work remarkable for its rapidity and thoroughness. June, 1902, two hundred and fourteen members were present at the meeting; June, 1903, this number had increased to five hundred and sixty-two. June, 1902, much time was consumed, and annoyance experienced, by the necessity of applicants for admission being passed on by a committee; June, 1903, all members on the list of the branches were at once given a membership badge—a minute only being consumed and no irritation. In June, 1902, the society did all its business in general session; June, 1903, the business was divided thus: the council looked after finance, publication, organization, and judicial matters; the house of delegates dealt with all legislative matters, and elected all officers, except president, decided on the next place of meeting, etc., while the immense general body elected the president, listened to addresses, engaged in scientific work and social fellowship. The confusion and turmoil of former years was abandoned in favor of a system which accomplished the objects of the meeting, in a manner perfectly equitable to every branch, after the fashion of a scientific organization. Naught occurred to darken the face, or disturb the heart of any member—*per contra* smiles and good cheer brightened the assemblage all the days. In June, 1902, doubt and anxiety prevailed; June, 1903, evident results filled all with hope for the future. Experience had proved the Michigan organization a success.

Previous observations rendered it improbable that officers could be found who would give of their time, energy, thought, money and sacrifice of private business with liberality adequate for the needs of the situation, but Michigan's experience shows that a president, vice-presidents, twelve councilors, with a secretary and treasurer, were found who failed not when the work was before them. As the society had no funds to pay their expenses, they individually met them, beyond the stipend of twenty-five dollars each to the councilors, nothing to president or vice-presidents, and naught extra to secretary or treasurer.

Not only did each councilor do his own work, but freely responded to the calls of brother councilors. The president always went wherever asked, as did the secretary, both rendering invaluable service. Thus Michigan had a corps of self-sacrificing men in the field from start to finish—so may any other state.

Most essential in this work is personal teaching—one who has learned and believed in organization carried it to those who had not learned or did not believe. The short cut of circular or journal article will fail either to organize or maintain such societies. To not a few was it a revelation to observe so many men, without hope of personal gain, toiling through Michigan, during an entire year, in organizing branches to the state society—but the fact gained hosts of adherents.

In general the officers were directed to do two things: (1) to make the society as valuable as possible, and (2) carry a knowledge of this to every physician in Michigan, with such persuasive power as to induce him to become an active member of his branch of the state society. To the utmost limit were they to make it more profitable and pleasant for each doctor to be in than outside the society. Actual results measure their extraordinary success.

It must not be supposed that no difficulties disturbed the work of organization, but in every case a fair hearing and full comprehension of the proposition won adherents. So universal was this experience of the councilors that they are sanguine of similar success in the future.

Most wholesome was the lesson to individuals, that unless members of a branch they could have no part in the meetings of other branches in the state society or the American Medical Association. To gain these relations not a few joined their branch society. To be thus supported by the larger bodies has been a pillar of strength to the branches.

The leaders in Michigan organization well understand their work has only begun; that physicians must be persuaded to work in their local branches, and those already therein encouraged to work out their own development, that of their branch, and the state society. The officers of the branches have this work primarily in charge. If they fail it is for the councilor, by such means as seem wisest in each case, to awaken interest and stimulate effort. In fact, one great problem before the councilor is to find the best method of securing and keeping the highest activity of the branches.

Should the councilor fail, his vice-president steps in to awaken him to duty. If he too fails, the president exercises his natural prerogative and stirs each to the desired activity. In Michigan it is expected that the president shall personally visit as many of the branches as possible, make a speech, read a paper, or hold a clinic, and in general use his office to increase the activity of the branches. Our late president set the pace for his successors in this direction.

Experience taught the councilor, when striving to organize or vivify a branch, that success followed a diversion from local quarrels and disputes to broader and larger questions affecting state or national interests. Fired with a larger thought, personal interests quietly dropped into their natural relationships. By such a method the writer has often seen a discordant group transformed, within an hour, into a smiling band of co-workers, ready to do and dare for the larger idea, that which its success demanded. In fact, the largest returns from organization spring directly from this law—as the organizers go out of themselves to help others their true selves come into view—selves that make for all that is best in the profession, in manhood and citizenship.

The council's report showed that last September it started a journal, under the management of the secretary-editor, which had succeeded beyond expectations, in awakening and continuing interest among the branches, and its future looks very promising. The same report showed that experience was teaching the council how to secure increasingly large returns from the funds at its disposal, and how to adjust the difficulties between individuals or branches for the common good.

Intelligent work, persistent and helpful to every physician in the state, is the secret of such success as has obtained in Michigan. To this end most of the officers of last year were re-elected, and the outcome demonstrates the wisdom of the act. The fundamental platform of modern organization is the selection of officers for their known fitness and ability, to serve, not as figureheads or little gods.

The power of seventeen hundred united physicians in Michigan, as compared with that of five hundred discordant ones, has indicated itself in many ways:

(1) It has given a self-confidence to the Michigan profession heretofore unfelt in its ability to help its members, the outside profession and the people. (2) It has spoken to the legislature and secured a more respectful answer, because it had votes, and because the chances were greater, that it expressed larger truth. (3) As six hundred members gathered in Detroit at its late meeting, the laity saw a vast concourse of physicians clearly trusting each other. It reasoned that if these learned men so evidently trust each other, we may trust them, so the people as rulers of the land had a lesson that the new profession, with modern organization, is certain to develop a profession in which "he that is greatest is servant of all."

LEARTUS CONNOR, A.B., M.D.,
Chairman Council Michigan State Medical Society.

The Demise of the "Philadelphia Medical Journal."

PHILADELPHIA, June 29, 1903.

To the Editor:—Certain inaccuracies in the statement made by the late editor-in-chief of the *Philadelphia Medical Journal*, in your issue for June 20, seem to need correction in order that the profession may be better able to point the moral which adorns this tale. I refer particularly to the words:

"Two and a half years ago the *Philadelphia Medical Journal* reached a crisis in its affairs which led to a change in editorial management. There were many prominent medical men in Philadelphia and elsewhere who were interested in keeping the journal alive; and in spite of the fact that its short career up to that time had been marked by threatening disaster (due largely to the opposing aims and temperaments of men who commanded its various departments), a determined effort was made to rehabilitate the journal and give it a new lease of life. At the same time, however, the command of its stock was allowed to remain in the hands of a few (and a very few) laymen."

It is true that the difficulty two and a half years ago was that of "opposing aims and temperaments," but these were the old division betwixt commercialism vs. ethics. It was this that culminated in the displacement of the editor by the commercial interests, in order (as was stated at the time), to install some one who might either be hoodwinked by them or who would be pliable to the demands of commercialism. The "impending disaster" was brought into existence solely as a reason to give for deposing an editor who refused to be subservient. These facts were made known to the late incumbent personally before he assumed the position of editor-in-chief, following my dismissal and the abrogation of the office of editor, and were also made known to the profession in general by a "protest" presented at the annual stockholders' meeting of the Philadelphia Medical Publishing Company, and thereafter sent to practically every physician in the United States and Canada. It will be remembered that this protest was directed chiefly against the condition outlined in the last sentence of the quotation from the communication of the late editor-in-chief—the placing of the absolute control of a medical journal in the hands of practically one stockholder, a layman.

Not a word or sign of dissent to the statements contained in that protest has ever been made, and this letter by the recent editor-in-chief is an unexpected confirmation of their absolute truth, and reveals the rapid degeneration of the journal during the two and one-half years following. The disastrous conditions which have made the *Philadelphia Medical Journal* "practically dead in the city of its birth" have developed within the past three years. They could, however, never have prevailed had not the indifferent and apparently consenting attitude of a few physicians confirmed the commercial element in a belief that "professional ethics" existed only in the mind of the deposed editor, and that the profession would believe anything they pleased to say, if it was only said often enough and loud enough. Indifferent authors would help them by contributing their articles, indifferent physicians would send in subscriptions, and a mint of money could be made out of them and out of advertisers with the aid of subservient professional helpers! When my incumbency as editor was terminated, the journal (according to report of its business manager) had close on 12,000 subscribers. That these were gained through confidence in the editorial conduct of that journal was shown by the fact that *American Medicine*, which two and a half years ago took up the spirit and aims laid down by the *Philadelphia Medical Journal*, had 12,000 subscribers in less than nine months from its inception. Having faith in the existence of professional sentiment and recognizing that, if it could build a journal like the *Philadelphia Medical Journal* was two and a half years ago, it could also maintain it, and desiring to avert the blight of commercialism from so fair a property, I made a proposition to the board of directors prior to the final act of my dismissal, offering to lease the journal from them for any period of years they should name, assuming entire editorial and business charge and guaranteeing them as rental an annual payment of 5 per cent. on the then capital stock of $60,000. Under the conditions that then existed, with one journal in Philadelphia and with a different business management, this could have been done.

The communication of the late editor-in-chief is but a continuation of the story told in my "protest," and emphasizes the warning of the dangers of commercialism in medicine as much by what it leaves unsaid as by the degrading conditions it reveals. Those in the profession and those dependent on the profession may read their lessons, the one of the evils resulting

from the unfaith of commercialism, the other that ethical sentiment is growing, and that though commercial cunning may apparently prevail for a time, its portion will eventually be meted out to it. GEORGE M. GOULD.

Indian Method of Treating Measles.

OGDEN, UTAH, June 28, 1903.

To the Editor:—Speaking of the Indian and his improvised Turkish bath, and the observations of McClanahan and Judd, I beg to say that when I was connected with the Winnebago and Omaha agencies some years ago the Indians there improvised a Turkish bath exactly as described by Dr. Judd in THE JOURNAL of June 27. Dr. Judd queries whether the Indian would go into cold water after this hot bath if the water were available. That is exactly what they all did at the Omaha reservation. I remember an epidemic of measles in which I had little to do other than look on, for they had a Medicine Man of their own and were impatient of any interference from me or any one. The disease was confined principally to the papooses under 10 or 12 years old. They did very little till the trouble was well established, then the patient was carried into an already prepared tepee of hides, usually buffalo skins, where it was rolled in a heavy blanket and laid in a rudely-constructed cradle made of the limbs of trees. Rocks had already been heated and now water was poured over them. Prior to this, however, the Medicine Man was in evidence and I had been relegated. He first scraped the vertex of the caput with a horn or piece of glass, and when the spot was thin enough the shell of a small horn, usually that of a young buffalo, was placed thereon after the air had been exhausted, I do not remember how, something after the manner of a cupping glass. Then the Medicine Man, assisted by the gifted of the tribe, sought to exercise the evil spirit that had entered into the little victim. This was done by the beating of tom-toms and other added instruments, including the human voice, that made the succeeding days and nights ones of horror. The flaps of the tepees were pinned down tightly to the ground, and after a little the odor inside, coming from a combination of steam, hides, heat and Indian, would stop a clock. The "hospital" tepee was always pitched on the bank of a stream of water, and as these epidemics of measles always occurred in winter (I do not remember of one at any other season) the stream was therefore frozen over. While the heating was going on some were cutting a hole through the ice. At the proper time the now half-dead young Indian was brought out, his blanket removed, and he was plunged into the icy water, perspiration and all. In a few minutes he would be returned to the tepee and the process repeated. The above will seem to many almost incredible, but it is true. Another incredible thing is that the little papooses thus treated sometimes recovered. A. S. CONDON, M.D.

Protracted Anesthesia.

AMESBURY, MASS., June 28, 1903.

To the Editor:—The subject embraced in the above title is one that I have not seen discussed in medical journals. I have no desire to act the part of the carping critic in considering modern methods of surgery; I am quite ready to acknowledge the wonderful progress made by the masters of the knife in the last forty years. To an old-time military surgeon the present results in treatment of wounds seem little less than a miracle. I have spent many hours removing maggots from suppurating stumps after operations, so that the dry antiseptic dressing seems like a page from a fairy tale.

The old-time surgeon had certain qualifications for which he should be given credit. He was a rapid operator. Prior to ether and chloroform the length of time required for an operation weighed heavily in the scale of results. Shock was rated in proportion to the length of suffering.

In the opinion of the writer the modern surgeon is losing sight of possible shock by too deliberate methods. In a large hospital a few days ago I saw a patient wheeled into the operating room fully anesthetized. The surgeons were preparing their hands and donning their robes with no attempt at haste. The theory was that the patient was not suffering and consequently they could take their time.

Now ether is either an advantage medically considered or a disadvantage. If it is of real decided benefit to the patient then protracted anesthesia is all right. If it is not, then this laggardly waste of time is wrong, and we are not giving our patients the best possible chance.

The writer has been under the surgeon's knife five different times with an experience varying from a few minutes to five hours' anesthesia, and from a personal standpoint is confident that the strain on the nervous system, even under ether, is no insignificant matter. Personally, I would not like to have a patient of mine lose three minutes' time under ether waiting for a surgeon. H. G. LESLIE, M.D.

Reciprocity—A Suggestion.

SELMA, ALA., June 30, 1903.

To the Editor:—For some time I have noticed that you have been trying to perfect some system of reciprocity between the licensing boards of different states. The scheme which I propose, if it could be carried out, might help those who have stood an examination in one state in getting a license in another. Should a physician practicing in one state wish to move to another he might be given the choice of standing the examination of the state into which he moves or be allowed to show his examination papers of the state in which he had already practiced; if these papers conform to the standard of the state into which he moves at the time of the examination he to be given a license in this state.

A recent graduate might make a very fine showing before one board, but should he try an examination in another state some five or six years later, though he knew considerably more than a man fresh from college, he would not be able to make as good a percentage. This manner of getting a license in another state without standing the examination is defective in that it applies to only those who have stood a written examination before an examining board. H. D. FURNISS.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

PRESCRIBING WHISKEY.

SHREVE, OHIO, June 26, 1903.

To the Editor:—Is it lawful for a physician to prescribe whiskey for a patient, then dispense the whiskey, charging the patient the retail price of the whiskey, but making no other charges, i. e., for professional services? N. E.

ANS.—A physician who would do this would be simply a dram seller and should take out a government and local license.

Book Notice.

THE PRACTICAL APPLICATION OF THE ROENTGEN RAYS IN THERAPEUTICS AND DIAGNOSIS. By William Allen Pusey, A.M., M.D., Professor of Dermatology in the University of Illinois; and Eugene W. Caldwell, B.S., Director of the Edward N. Gibbs X-Ray Memorial Laboratory of the University and Bellevue Hospital Medical College, New York. Cloth. Pp. 591. With 180 Illustrations, Nearly all Clinical. Price, $4.50 net. Philadelphia: W. B. Saunders & Co. 1903.

This volume is practically two books, one being devoted to x-rays as a diagnostic and the other as a therapeutic agent. Part one is written by Director Caldwell of the Gibbs X-ray Laboratory of New York, a man thoroughly competent, through practical experience, to write on the subject assigned him. In an introductory chapter is given a brief review of the experimental work which led up to the discovery of x-rays, then follow a description of the apparatus used, one chaptar being devoted to the Essentials of an X-ray Outfit, another to X-ray Tubes, one to Induction Coils, Interrupters and Their Management, one each to Static Machines and Their Management, to Fluoroscopy, to Photographic Materials and Their Manipulation, and sources from which the electric current may be obtained.

The chapter on Radiography is a most important and valuable one. In it are given in detail practical suggestions for

radiography, including specific directions for making radiographs of every part of the body. In the chapter on *x*-ray tubes is a description of the different tubes in use, the advantages and disadvantages of the several patterns and makes. In it are mentioned and described the tubes requisite for special work, such as for the rectum, vagina, throat, etc. Besides the ordinary drawings, this chapter is illustrated with several full-page illustrations, showing in colors the appearance of tubes under various conditions. In the chapter on Photographic Materials are considered developers and developing fixing plates, printing, etc. In the last chapter of part one will be found sensible and helpful suggestions regarding the choice of an *x*-ray outfit. In brief, part one is a concisely written description of the various appliances needed in an outfit for *x*-ray work, how to use and how to take care of them. The subject is presented in a manner sufficiently elementary to satisfy even those who have but little knowledge of electricity.

In the second part, which occupies about two-thirds of the book, is given a résumé of the literature already accumulated on *x*-rays as a therapeutic agent. In discussing the effects of *X*-rays on Tissues, the Histologic Changes Produced in Tissues by the *X*-rays, the Effects of *X*-rays on Bacteria, and the Causes of the Phenomena Observed in Tissues After Exposure to *X*-rays—the headings of the first four chapters—Pusey has reviewed and analyzed the experimental work, observations and conclusions of American and foreign workers bearing on these subjects, including, of course, his own work. In the chapter on the Technic of *X*-ray Exposures for Therapeutic Purposes, besides his own, he gives the methods of such Europeans as Kienböck, Scholtz, Oudin, and Schiff and Freund, and of such Americans as Williams and Beck. He gives in detail the technic of the application of the *x*-rays to the treatment of diseased conditions, covering all points not given in part one by Caldwell. The rest of the book is devoted to the treatment of diseased conditions under the following chapter headings: Treatment of *X*-ray Burns, Indications for the Therapeutic Use of *X*-rays, Affections of the Appendages of the Skin, Inflammatory Diseases of the Skin, Tuberculosis and Similar Diseases, Cutaneous Carcinoma, Carcinoma of the Breast and in the Thorax, Deep-seated Carcinoma, Sarcoma and Other Granulomata, the Prophylactic Use of *X*-rays After Operations for Malignant Diseases and Pseudo-leukemia and Various Other Affections. In these chapters are given in brief the results obtained by the use of the *x*-ray by others and their views as to the efficacy or otherwise of the agent in all conditions in which it has been used or for which it has been recommended. The author gives his own experience and results in detail, accompanied by reports of cases. In quoting others, the author does not hesitate to oppose the position held by them, but in doing so he gives the reasons for his opposition, and not with dogmatic statements.

The position taken by the author regarding the value of the *x*-rays as a therapeutic agent is a conservative one; while its wonderful effectiveness is recognized, its limitations are also appreciated. In considering the possibilities of *x*-ray treatment in tuberculosis of the lungs, he says: "It certainly does not hold out sufficient hopes of relief to warrant its use at the expense of residence in a bad climate, or abandonment of better tried measures." As to syphilis: "There is certainly no reason to substitute *x*-rays for the efficient method of treating these lesions that we already have." These are samples of the conservative statements that occur quite often. The book as a whole can be recommended as being one of the best and most practical thus far published on the *x*-ray as a diagnostic and therapeutic agent in that it contains a sufficiently detailed description of the apparatus used, the technic, a concise and critical review of the experience and opinions of those who have used it, and a conservative statement of its possibilities and limitations as a therapeutic agent in all conditions in which it has been used or suggested. It is a practical timely book that will be appreciated and welcomed by all who are engaged in *x*-ray work, as well as by those who are interested only indirectly.

Marriages.

GEORGE F. TOALSON, M.D., to Miss Lulu Wheeler, both of Mexico, Mo., June 16.

WILLIAM A. MCMILLAN, M.D., to Miss Ellinor Graham Owen, at Baltimore, June 24.

JOSEPH BRADY, M.D., to Miss Eugenie Brown, both of San Francisco, Cal., June 25.

JOHN L. CHESTER, M.D., to Miss Kathryn E. Butler, both of Emmett, Mich., June 16.

JOSEPH IRWIN FRANCE, M.D., to Mrs. Evalyn S. Tome, at Port Deposit, Md., June 24.

ARTHUR C. JOHNSON, M.D., Newark, Ill., to Miss May Dean of Monmouth, Ill., June 15.

THOMAS BOYD MORRIS, M.D., Atlantic, Iowa, to Miss Esther McLean of Joliet, Ill., May 1.

CHARLES ROBERSON, M.D., Greensboro, N. C., to Miss Mabel Hill, at Danville, Va., June 17.

FLOYD J. ROBERTS, M.D., Cando, N. D., to Miss Ruby Rutledge of Grand Forks, N. D., June 25.

HENRY S. DOWNING, M.D., Los Angeles, Cal., to Miss Elsie Clarke of Springfield, Ill., June 23.

HENRY P. BEIRNE, M.D., Quincy, Ill., to Miss Hildred Marie Jones of Milwaukee, Wis., June 23.

STACY HEMENWAY, M.D., Klamath, Ore., to Miss Irene Chitwood of Klamath Falls, Ore., June 4.

JAMES COALE SAPPINGTON, M.D., to Miss Claire Sappington, at Liberty, Frederick County, Md., June 24.

GRANVILLE N. RYAN, M.D., Des Moines, Iowa, to Miss Miriam Pickens of Louisville, Ky., June 10.

PHILIP VEILE JANSE, M.D., Luverne, Iowa, to Miss Margaret Belle Mason of Fort Madison, Iowa, June 23.

TORANA GROTHAUS, M.D., to JOHN DULIN, M.D., both of Sigourney, Iowa, at Iowa City, Iowa, June 17.

B. F. WALKER, M.D., Laton, Cal., to Miss Edith Alberta Crews of Riverdale, Cal., at Fresno, Cal., June 24.

WILLIAM HOLMES YEAKLEY, M.D., Davis, W. Va., to Miss Eleanor Straith Ranson, at Staunton, Va., June 17.

WILLIAM JEFFRIES CHEWNING, M.D., Fredericksburg, Va., to Miss Anne Page Meetze of Washington, D. C., June 17.

PAULETT CLARK, M.D., Lynchburg, Va., to Miss Fannie Yuille of Campbell County, Va., at Washington, D. C., June 16.

Deaths.

Ewing L. Thompson, M.D. New Orleans (La.) School of Medicine, 1861, of Dallas, Texas, surgeon in the Confederate service during the Civil War, died suddenly at Mineral Wells, Texas, June 17, from apoplexy, aged 62. The Dallas Medical and Surgical Association held a special meeting, June 18, to make arrangements for Dr. Thompson's funeral and to prepare resolutions of respect.

Stephen E. Robinson, M.D. Rush Medical College, Chicago, 1867, a member of the American Medical Association, ex-president of the Iowa State Medical Society; member of the International Association of Railway Surgeons, Iowa State Association of Railway Surgeons, Fayette County Medical Society, etc., died at his home in West Union, Iowa, June 7, aged 65.

Frederick A. Davis, M.D. Medical College of Alabama, Mobile, 1861, of Newport, Ky., who served throughout the Civil War as Surgeon, U. S. V., was for 16 years district physician, and for four years coroner of Campbell County, Ky., died at Shepard, Ohio, where he was under treatment for kidney disease, June 24, aged 66.

Nathaniel P. Washburn, M.D. New York University, 1891, of Stamford, Conn., who had been traveling for nearly ten years in search of health, visiting Saranac Lake, N. Y., Albuquerque, N. M., and Boulder, Colo., in his quest, died from tuberculosis, June 22, at San Antonio, Texas.

John H. Vincent, M.D. Michigan College of Medicine and Surgery, Detroit, 1902, of Red Ridge, Mich., on June 18, while responding to an urgent professional call, was thrown from his horse, sustaining a fracture of the base of the skull, from which he died two days later.

Walter F. Blunt, M.D. Galveston (Texas) Medical College, 1874, for twenty-five years state health officer, who bore a

spotless record in quarantine service of Texas, died, June 24, at Lockhart, Texas, from Bright's disease, after a long illness.

Carl Schwalbe, M.D. University of Bonn, Germany, 1862, a member of the American Medical Association, a surgeon in the German service during the Franco-Prussian War, died, June 14, at his home in Los Angeles, Cal., from tuberculosis, aged 65.

Stephen J. Dunn, M.D. Baltimore Medical College, 1896, of Springfield, Mass., a member of the Hampden District and Massachusetts medical societies, died at St. Francis' Hospital, Hartford, Conn., June 27, after an illness of two months.

Edwin A. Sailor, M.D. University of Iowa, Iowa City, 1901, Clarence, Iowa, formerly assistant physician at the Clarinda State Hospital for the Insane, died from typhoid fever at a hospital in Iowa City, June 22, aged 30.

Hans H. Littlefield, M.D., 1887, for many years a member of the American Medical Association, died at his home in Beardstown, Ill., June 26, aged 79. He served two years as a surgeon of volunteers during the Civil War.

William S. Wolfe, M.D. Jefferson Medical College, Philadelphia, 1897, of Fleetwood, Pa., died from tuberculosis, June 12, while on his way home from New Mexico, where he had gone eight months before for his health.

Sumner Pixley, M.D. Philadelphia Medical School, surgeon of the 110th Ohio Volunteer Infantry in the Civil War, died at his home in Peninsula, Ohio, June 12, aged 87. He retired from active practice in 1890.

William L. Towndrow, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1856, of Snohomish, Wash., a surgeon in the Civil War, died at the City Hospital, Everett, Wash., June 11, from diabetes, aged 80.

James Calderwood, M.D. University of Cincinnati, 1870, of Steele, Ind., died at the home of his father in Blue Creek township, May 31, from stomach trouble, after an illness of a week, aged 64.

Charles Legg, M.D., formerly of Stringtown, German township, Richland County, Ill., died at the Illinois Southern Hospital for the Insane, Anna, June 14, after a long illness, aged 78.

J. D. Vinton, M.D. Philadelphia University of Medicine and Surgery, 1854, of Kimberton, Pa., died at the Phoenix Hospital, West Chester, Pa. June 14, after a long illness, aged 74.

Thomas W. Hewitt, M.D. Louisville Medical College, 1861, surgeon U. S. Army, retired, died at his home in San Antonio, Texas, June 21, from congestion of the brain, aged 64.

H. Cloud Rainwater, M.D. Tulane University, New Orleans, 1891, died at his home in Morrillton, Ark., June 7, from consumption, after an illness of two years.

Charles W. Shaw, M.D. Ohio Medical University, Columbus, 1898, of Madison Mills, Ohio, died at his former home, near Logan, June 2, from Bright's disease.

Alonzo Shaffer, M.D. University of Pennsylvania, Philadelphia, 1895, died at his home in Essex, Conn., June 26, after an illness of two months, aged 32.

Louis Goeschel, M.D. Chicago Homeopathic College, 1878, died at his home in Mandan, N. D., June 17, from cancer of the tongue, aged 47.

Hubbard A. Foster, M.D. Harvard University Medical School, Boston, 1871, died suddenly at his home in Buffalo, N. Y., June 16, aged 53.

J. D. Mundy, M.D. Kentucky School of Medicine, Louisville, 1878, died at his home in Denver, N. C., June 25, after a lingering illness.

Benjamin F. Graves, M.D., died at his home in Hamline, W. Va., from typhoid fever, May 24, after a short illness, aged 25.

S. A. Taylor, M.D., of East Point, Ga., committed suicide while despondent, June 20, by shooting himself through the head.

Gilbert R. Woolsey, M.D. Hahnemann Medical College, Chicago, 1868, of Normal, Ill., died at Cambridge, Ill., June 7.

Henry K. Middleton, M.D. University of Louisville, 1871, died at his home in Kirksville, Ky., June 25, aged 59.

Louis R. Ford, M.D. Medical College of Georgia, Augusta, 1870, died at his home in Waynesboro, Ga., June 26.

Juan Jose Ramirez de Arellano, M.D., died at his home in the City of Mexico, from typhus fever, May 23.

D. H. Herrell, M.D., 1878, died at his home in Hanna City, Ill., June 22, aged about 60.

State Boards of Registration.

Minnesota.—The Minnesota State Board of Medical Examiners held their regular examination at St. Paul, June 2, 3 and 4, 1903. The results are reported by Dr. C. J. Ringnell, the secretary, as follows: Number of subjects examined, 12; total number of questions, 95; percentage required to pass, 75; total number examined, 129; passed, 111; failed, 18; the list of successful and unsuccessful applicants with their colleges and schools of practice is as follows:

Steenberg, H. S., Milwaukee.

Medical Organization.

Reorganization in Minnesota.

Minnesota was the last of four great states to set aside its action of partial reorganization of last year and adopt the constitution and by-laws recommended by the American Medical Association in full. The annual meeting was held at St. Paul, June 17 to 19.

While much had been accomplished during the year, and the membership had greatly increased, the new plan of organization was defective and unsatisfactory. No provision was made for a house of delegates or council, and membership in county societies was left optional. As a partial offset to these defects, and especially to the lack of a council, Dr. W. S. Fullerton, an efficient and enthusiastic worker, was appointed state organizer. Although his work was single-handed, and largely gratuitous, he had visited and organized fifty-eight counties during the year, and had laid the foundation for a complete organization.

After his return from the New Orleans meeting, Dr. J. W. Andrews, president of the State Association, began an active campaign for the adoption of the uniform plan of organization. His annual address was mainly devoted to this, and was an able presentation of the subject. At its close, a committee was appointed to consider the question, with instructions to report during the meeting. On the following day the committee reported, recommending that the action of last year be rescinded and that the uniform plan of the Association be substituted therefor. This was done by a unanimous vote. The committee also recommended that the state be divided into eight councilor districts, arranged according to the lines of travel, and that, in partial recognition for the value of his services in the past, Dr. Fullerton be made chairman of the first council.

The meeting was fairly well attended and was interesting throughout, in spite of a bad section arrangement which has found its way into many state associations. Under the old plan of organization the society was divided into three sections, the first day being devoted to surgery, the second to internal medicine, and the third to state medicine. This would probably be an unfortunate arrangement, even for a large meeting, for obvious reasons, but is especially so where the attendance is not large. Such meetings are for the entertainment and benefit of all, but particularly for the general practitioners from town and country districts, and the work in the different branches should be so interlarded in the program as to engage the attention of all classes, at least during a large part of every day.

The officials elected for the ensuing year are as follows: President, Charles Lyman Greene, St. Paul; vice-presidents, Charles Hill, Pine Island; Jeannette M. McLaren, St. Paul, and Walter H. Darling, St. Peter; secretary, Thomas McDavitt, St. Paul; treasurer, Richard J. Hill, Minneapolis.

Council.

Wm. S. Fullerton, St. Paul; Frederick A. Knights, Minneapolis; Alfred E. Spaulding, Luverne; Adolph O. Bjelland, Mankato; Eugene H. Hensel, Alexandria; Harper M. Workman, Tracy; Walter Courtney, Brainerd, and Franklin A. Dodge, Le Sueur.

It may be interesting to note that twenty-eight states have now adopted the uniform plan of organization. This includes all of the great states in the Ohio and Mississippi valleys, all the Lake and Gulf states, two of the three Pacific states, besides North Carolina, New Jersey, New Hampshire, Colorado and Idaho, in other sections. If systematic work can be kept up within all of these states for a few years, with the intelligent enthusiasm now promised, we shall have an organized profession.

J. N. McCORMACK.

Societies.

Humboldt County (Cal.) Medical Society.—This society, at its regular meeting, June 9, adopted the amended constitution and by-laws, so that it now is in conformity with the state society.

Buncombe County (N. C.) Medical Society.—At its meeting in Asheville, June 15, the society adopted the changes in its constitution and by-laws necessary to make them conform to those proposed by the American Medical Association.

Cheboygan County (Mich.) Medical Society.—At the annual meeting held in Cheboygan, June 16, Dr. Wilbur F. Reed was elected president, Dr. Ira C. Williams, vice-president, and Dr. Charles B. Tweedale, secretary-treasurer, all of Cheboygan.

Lane County (Ore.) Medical Association.—At the annual meeting held in Eugene, June 17, Dr. Waldo L. Cheshire, Eugene, was elected president; Dr. George Wall, Cottage Grove, vice-president, and Dr. John W. Harris, Eugene, secretary and treasurer.

Cedar County (Neb.) Medical Society.—This society, a component part of the state medical society, met at Hartington, June 24. Every physician in the county is a member of the society. The next meeting is to be held in Randolph on September 24.

Columbus (Ohio) Academy of Medicine.—The consolidation of the Franklin County Medical Society with the Columbus Academy of Medicine, was perfected at a meeting of the latter society, June 1, when the joint committee on membership reported favorably on 21 applications.

Johnson County (Kan.) Auxiliary Medical Society.—Physicians of Johnson County met at Olathe, June 11, and organized

this society, with Dr. H. E. Williamson, president; Dr. Jessie Thomas, vice-president; Dr. Frank F. Greene, secretary, and Dr. B. Frank Stout, treasurer, all of Olathe.

Elkhart County (Ind.) Medical Society.—At its meeting, June 25, the society decided to change its conditions of membership to accord with those of the state and national societies. Dr. John C. Fleming, Elkhart, was elected president; Dr. I. Wright Short, Elkhart, vice-president, and Dr. Yoder, Goshen, secretary-treasurer.

Iberville Parish (La.) Medical Society.—The physicians of Iberville Parish met at Plaquemine, June 17, and organized a parish medical society, with the following officers: Dr. Arthur A. Allain, Bayou Goula, president; Dr. Francis J. Keamey, Plaquemine, vice-president, and Dr. Eugene Halloway, Plaquemine, secretary and treasurer.

Iowa Health Officers' and City Physicians' Association.—The health officers and city physicians of Iowa met at Des Moines, June 16, effected a temporary organization, with Dr. Joseph A. Valenta, Iowa City, chairman, and Dr. Cassius T. Lesan, Mount Ayr, secretary, and appointed committees on constitution and by-laws, permanent organization and finance.

Branch County (Mich.) Medical Society.—This society, recently organized under the constitution and by-laws proposed by the American Medical Association, at its meeting in Coldwater, June 16, elected Dr. Stephen H. Clizbe, Coldwater, president; Dr. Henry W. Whitmore, Quincy, vice-president, and Dr. Samuel Schultz, Coldwater, secretary and treasurer.

Lewis County (Ky.) Medical Society.—About half the physicians of Lewis County met at Vanceburg, June 15, and organized a county medical society, to be in affiliation with the Kentucky State Medical Society and the American Medical Association. Dr. James W. Kincaid, Catlettsburg, councilor for the district, was present and explained the plan of organization. Dr. Lewis A. Grimes, Concord, was elected president; Dr. John F. Irvine, Tolesboro, vice-president; Dr. Aaron F. Hill, Vanceburg, secretary, and John C. Graham, Trinity, treasurer.

International Association of Railway Surgeons.—The annual meeting was held in Indianapolis, June 18. The next meeting will be held in Chicago in May, 1904. The following officers were elected: President, Dr. James H. Ford, Indianapolis; vice-presidents, Drs. James M. Weaver, Dayton, Ohio; Edwin F. Yancey, Sedalia, Mo.; M. V. B. Newcomer, Tipton, Ind.; Charles R. Dickson, Toronto, Ont.; William R. Hamilton, Pittsburg, Pa.; David F. Stuart, Houston, Texas, and Hugh M. Taylor, Richmond, Va.; secretary, Dr. Louis J. Mitchell, Chicago, and treasurer, Dr. James A. Duncan, Toledo, Ohio.

Frisco Medical Association.—The second annual meeting of the surgeons of the Frisco system was held in Springfield, Mo., June 23 and 24. The following officers were elected: President, Dr. George W. Cale, Springfield; vice-presidents—for Alabama, Dr. Edward P. Lacey, Bessemer; for Arkansas, Dr. H. Clay Dunavant, Osceola; for Indian Territory, Dr. Fred S. Clinton, Tulsa; for Kansas, Dr. George C. Purdue, Wichita; for Mississippi, Dr. Samuel A. Gassaway, New Albany; for Missouri, Dr. George O. Coffin, Kansas City; for Oklahoma, Dr. A. H. Bourgardt, Cordell; for Tennessee, Dr. W. Britt Burns, Memphis, and for Texas, Dr. Willliam A. Duringer, Fort Worth; secretary, Dr. Roche W. Hogeboom, Springfield, Mo., and treasurer, Dr. Walter A. Camp, Springfield, Mo.

Connecticut Medical Society.—The one-hundred and eleventh annual meeting was held in Hartford, May 27 and 28, under the presidency of Dr. Gould A. Shelton, Shelton. The committee on tuberculosis reported that, of the 696 members of the society, only 115 had returned replies to the circular sent out by the commitee, which did not feel justified in assuming that the conclusions drawn from the collective investigations represented the concensus of opinion of the society. The president, in his address, commented favorably on the organization scheme as proposed by the American Medical Association, and on the elevation of the standard of medical education approved by the American Association of Medical Colleges and by the American Medical Association. The committee on revision of constitution and by-laws on the plan recommended by the American Medical Association, reported that it would not be able to make a complete report until the next meeting. The following officers were elected: President, Dr. Samuel B. St. John, Hartford; vice-president, Dr. William H. Carmalt, New Haven; secretary (for four years), Dr. Nathaniel E. Wordin, Bridgeport; assistant secretary, Dr. Henry S. Miles, Bridgeport; treasurer, Dr. William W. Knight, Hartford, and delegate to the American Medical Association, Dr. L. Duncan Bulkley, Norfolk. At the annual banquet, Dr. Oliver C. Smith, Hartford, presided as toastmaster. Charles T. Wells, a son of Dr. Horace Wells the Hartford discoverer of anesthesia, presented the society with a portrait of his father taken in 1825.

Ontario Medical Association.—The annual meeting was held in Toronto on June 16, 17 and 18. Dr. J. C. Mitchell of Toronto presided, and Dr. Harold C. Parsons, Toronto, acted as secretary. Dr. J. H. Musser, Philadelphia, President-elect of the American Medical Association, was present and delivered a very able and practical address on the treatment of pneumonia. In moving a vote of thanks to Dr. Musser, Dr. N. A. Powell jocularly referred to the powerful influence the Ontario Medical Association wielded in electing the Presidents of the American Medical Association. Some years ago Dr. Henry O. Marcy, Boston, was a guest of the association, and the American Medical Association promptly made him its President. Then followed Dr. John A. Wyeth, with a similar result, and now the good record had been kept up in Dr. Musser. Dr. Thomas S. Cullen, Baltimore, presented a valuable paper on "Uterine Myomata and Their Treatment." Mr. I. H. Cameron, in moving a vote of thanks to Dr. Cullen, stated he believed it was the best contribution on the subject ever written. A very interesting address on the medical witness under cross-examination was delivered by Hon. W. R. Riddell, K. C., Toronto, who divided all liars into three classes, liars, d——d liars and medical experts. A very interesting and profitable discussion took place on the morning of the third day on the subject of arteriosclerosis. The etiology and pathology was dealt with by Dr. H. B. Anderson of Toronto; the cardiac aspect by Dr. T. W. G. McKay, Oshawa, Ont.; the renal aspect by Dr. John Caven, Toronto; the cerebral aspect by Dr. Hugh McCallum, London, Ont.; the ophthalmic lesions by J. Cameron Connell, Kingston, Ont.; and therapeutics by Dr. John L. Davison, Toronto. The following officers were elected: President, Dr. James F. W. Ross, Toronto; secretary, Dr. Charles P. Lusk, Toronto; treasurer, Dr. Andrew R. Gordon, Toronto. Toronto was selected as the next place of meeting.

NORTHWEST MEDICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, June 2, 1903.

The President, Dr. Wendell Reber, in the Chair.

Symposium on Epilepsy.

"The Treatment of Epilepsy" was the title of a paper read by Dr. Luther C. Peter, in which he directed attention to the fact that the treatment of the disease must be largely prophylactic, first, by preventing the causes which give rise to the convulsion, and second, by preventing the subsequent convulsions, with the consequent mental and physical changes. He believed that much more could be done for the patients by careful attention to the diet, daily bath, sleep and environment, especially in children, than by medical measures, and these measures are particularly important if the child has a neurotic predisposition. He believed tea and coffee acted in many cases as inducing factors, and in some cases were the only causes of epilepsy in children; the great amount of mental work done by children with the present school system, he believed, also was accountable for a considerable number of these cases. After the epileptic habit is formed the general management of the case is important, and while he believed that drugs played an important rôle in the cure of these cases, he felt that the general management was the most important factor of every complete recovery. The author recommended the closest scrutiny of all parts of the body in order to detect any cause for epilepsy, and stated that he had seen cures follow the correction of refractive errors, removal of adherent foreskin, removal of constipation, etc., the success depending entirely upon the early recognition of the condition and removal of the cause. The toxic form, including the alcoholic type, he believed to be especially amenable to general treatment. It is pretty generally conceded that the convulsion has its origin in the cortical cells, and, therefore, the class of drugs which do the most good are nerve sedatives, the drug most extensively used being the bromid salts. He stated that he believed in many instances the mental dullness was due more to the excess of the bromids than to the epilepsy, and referred to the fact that few patients could take this remedy in larger amounts than 30 to 40 grains per day for any length

of time without producing bromidism; the addition of several drams of infusion of digitalis often intensifies the sedative action, without aggravating the bromidism; a minim or two of Fowler's solution will prevent the acne. Chloral will act beneficially for a time in controlling the convulsions, and if the patient has mental warning of the approach of an attack and it is given in sufficiently large doses it will often prevent the convulsion. He stated that he had used the fluid extract of solanum in a considerable number of cases, and in adults had found that as good results could be secured with from 2 to 4 drams of this drug as from 10 to 15 grains of potassium bromid, and its use can be continued indefinitely without the depressing mental effects. Its use has been followed by equally gratifying results in children, who usually stand the bromids so poorly. In those patients who have a considerable period of premonition, inhalation of nitrite of amyl is of much value in warding off the attack.

Diagnosis of Atypical Epilepsy.

DR. A. C. BUCKLEY read a paper on the above subject, in which he called attention to the necessity for early diagnosis and correction before the nervous mechanism had formed the epileptic habit. After giving in detail the symptoms of a typical attack of epilepsy, he stated that there were many cases which were not recognized for months, or perhaps years, owing to the fact that the attacks may be of such a nature as not to be noticed by the patient or his family, or may occur only during the sleeping hours, when, except for the fact that he feels fatigued and has marked muscular soreness upon awakening, the patient when he seeks medical advice is not aware of his true condition. He believed that the minor attacks were less responsive to treatment than the major attacks. They usually consist of momentary unconsciousness which very often is not recognizable, and it is in these that the greatest deviation from the set symptoms occur. Nocturnal epilepsy, when the symptoms are not sufficient to be recognized by the patient, can only be diagnosed by the after-signs, such as soreness of the tongue, usually on one side, frequently blood stains on the pillow, if the tongue has been bitten, minute conjunctival extravasations, voiding of urine in bed, and even these are frequently absent. He believed that a confusing factor in diagnosis was the differentiation between the minor epileptic attacks and the syncopal attacks; the epileptic attacks occur independent of the surroundings and in the absence of any predisposing causes, such as emotion, physical exertion, overheated rooms, hot, humid weather, etc., which frequently produce syncopal attacks. In the latter condition there is usually an irregular pulse and clammy skin, which is not present in epilepsy. In epilepsy the loss of consciousness is sudden and complete, and returns quickly, while in syncope it is usually preceded by a subjective feeling of faintness. Epilepsy may be preceded by an aura which may be described as a feeling of faintness, but there is usually associated with it a sensation of fear or strangeness which is not present in syncope. Distinct vertigo is in favor of epilepsy, although care must be taken to distinguish the vertigo from dizziness, which is sometimes present in syncope. He considered the automatic type of epilepsy of great importance. He believed that hysteroid could usually be distinguished from epileptic seizures by the fact that the former are usually coordinated.

DR. CHARLES W. BURR referred to the fact that the etiology of epilepsy was still very much in the dark, and believed that the greatest hope lay in the prevention, rather than the cure, of epilepsy, and in children predisposed to this condition, it is especially important that they should live out of town, have nourishing food and avoid mental overwork. He believed that alcohol played a considerable rôle in the production of epileptic seizures, and reported the case of a shoemaker, who would have attacks only after a drunken debauch. He felt that many of the cases of dementia were much accentuated by the long-continued use of bromids, and while he had not attained very good success with horse-nettle, thought this fact could probably be accounted for in that he had not given it in sufficiently large doses. In regard to diet, he did not believe that the patient should be required to forego red meat altogether, although he felt that its use should be restricted. He referred to several cases of post-epileptic automatisms, one man would go through the motions of pulling a rope for three or four minutes every time he would have an attack, and he expressed the opinion that in some instances this condition was responsible for the perpetration of innocent crime.

DR. SAMUEL WOLF felt that a careful study of the aura in connection with the sensory nerves might reveal something in regard to the etiology of the condition, and expressed the opinion that the attack originates in the peripheral sensory nerves rather than in the cortical cells. He referred to the fact that a large number of curious conditions have been recognized as epileptic equivalents directing particular attention to the fact that an Italian writer had recently advanced the theory that a good many of the cases of tachycardia are really cases of epilepsy, and reported a case of tachycardia which had recently come under his observation which he rather inclined to think was of this class. In the treatment of epilepsy he believed the bromids to be the foremost remedies, and if bromidism occurs, the addition of one or two drops of Fowler's solution with each dose is of value. Atropin is also frequently of advantage in conjunction with the bromids.

DR. WENDELL REBER stated that he had made a careful study of the ocular condition of about fifty epileptics for about a year, and found pupillary inco-ordination in about one to three, optical imbalance in about 35 per cent., and in a good many hypermetropic astigmatism was present. He did not attach much importance to these eye conditions, however, as all of them frequently exist in other conditions. He referred to the fact that a majority of epileptics were great overfeeders and not very active.

DR. LEWIS H. GOOD reported a case of a man who became intoxicated, and after he went home fell over in a fit; after this was over he was very violent for about an hour, breaking up furniture, etc., after which he fell into a deep sleep or comatose condition. He also reported another case, apparently hysterical, in which the symptom is incessant talking for about half an hour, the acts being both nocturnal and diurnal. The patient was run over by a wagon when a child and at puberty had amenorrhea and dysmenorrhea, since which time she has had these attacks.

DR. SOLOMON NEWMAYER referred to the rarity of the occurrence of epilepsy among the Hebrew race. He reported the case of a man who was suddenly taken ill on a very hot day; he became unconscious, had a temperature of 104 degrees; spermic fever was suspected and the usual treatment applied. After about an hour he revived, the case proving to be one of epilepsy.

DR. J. FRANK WALLIS reported three cases of convulsions, one of which he attributed to the patient eating cabbage, the other to eating sausage and pretzels, and the third to the fact that the patient had eaten a very hearty dinner. All of these cases were relieved by rectal injection, and the suggestion was made as to whether they were cases of true epilepsy or not.

DR. NATHAN G. WARD referred to cures that had been reported by the removal of obstructions of the naso-pharynx or by the removal of obstructions from the ear, the condition in most of these cases being obstruction or deflection of the septum, adenoids, enlarged tonsils and a few cases of pharyngeal abscess and suppurated ears. He believed that the greatest good could be secured by the use of prophylactic measures tending to prevent the attacks.

DR. CHARLES C. BIEDERT reported the cases of two brothers, both of a neurotic temperament, in which the attacks were frequently superinduced by disputes with their wives, in which the cold-water treatment was administered with gratifying results. He also referred to a case caused by alcoholism which was benefited by this same method.

DR. HOWARD S. KINNE felt that a very important factor in the prophylactic treatment of epilepsy was the placing of all infants on a properly nourishing diet, as nearly similar as possible to the mother's milk. He believed that one reason why epilepsy was less frequent among the Hebrew race was owing to the fact that the mothers usually nurse their chil-

dren. Alcohol he did not believe played a very important part in the production of epilepsy in the subject himself, but was more manifest in his descendants.

DR. WILLIAM EGBERT ROBERTSON called attention to the fact that convulsive attacks produced by bradycardia are very similar to the epileptic seizures. He believed that too often convulsions in children were attributed to teething and very little attention paid to them, which he felt accounted for at least some of the cases of epilepsy. He felt that tea and coffee played but a small rôle in the production of epilepsy in those not predisposed to the disease.

DR. LUTHER C. PETER, in closing, stated that he did not believe solanum to be any better drug than bromid, but its greatest merit consisted in the fact that it could be given in sufficiently large doses to benefit the patient for a long time, without producing any mental effects. In regard to alcohol as a causative factor, he stated he had three cases under his observation at the present time, who were subject to the seizures only after a debauch, but did not feel prepared to say that this was the cause of the epilepsy.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

Twelfth Annual Meeting, held in Boston, May 19, 20 and 21, 1903.

The President, Brigadier General Robert A. Blood, Surgeon General of Massachusetts, in the Chair.

Welcome.

The opening session was held in Faneuil Hall, where the association was welcomed to Boston by Governor J. L. Bates and Dr. George E. Francis, president of the state medical society.

President's Address.

GEN. ROBERT A. BLOOD discussed the value of the association in bringing into harmony the work of the medical officers of the regular establishment, the national guard and the volunteers, considering this in the light of his own experience during the Civil and Spanish-American wars, and held that, with the facilities afforded by the association for uniform conduct, nothing but the failure of the government to make prompt, proper and ample appropriations could interfere with the highest efficiency of the medical service.

Public Service Medical School.

LIEUT.-COL. JOHN VAN R. HOFF, U. S. A., reported for this committee on the work of the Army and Navy medical schools for the year, and detailed the recommendations of the Surgeon-General of the Army relative to the establishment of an army medical school, in which a candidate should pass one year as a medical cadet and four years as a medical officer. Colonel Hoff, however, proposes to go still further and educate government medical officers *a binitio*, at an institution similar to the military academy at West Point, at which preparation would be made for all branches of the medico-military service.

COL. R. R. DE WREDEN, of Russia, described the Imperial Medical School at St. Petersburg, which gives its students their entire medical and military education, and whose graduates are assigned to hospitals or regiments in accordance with their class standing; the seven highest in each class being sent abroad to elaborate their studies and return as adjunct professors; the next highest being assigned to the hospitals, and the remainder to regiments.

Education of the Medical Officer of the Army.

MAJOR WILLIAM C. BORDEN, U. S. A., gave a succinct survey of the post-graduate instruction of the United States Army, dwelling especially on the work of the Army Medical School and incidentally referring to similar schools of other countries. He urged the extension of the facilities of the school to the medical officers of the militia.

This article was discussed at length by representatives of the United States Navy, various volunteer officers and the representatives from Canada and England. In closing the discussion Major Borden admitted the necessity of thorough professional training in the military medical officer as a prime factor, but recognized that in military service, administrative work was also of great importance.

The Acting Assistant Surgeon.

MAJOR AZEL AMES, U. S. V., commented on the anomalous position of the contract surgeon of the United States Army, observing that he had all the responsibilities and shared all the dangers of his commissioned colleague without either the honors or rewards to which the latter may look forward. He can anticipate no promotion, has no increase in pay for length of service, has no retirement nor pension when he becomes worn out in the service. The author forcibly urged the improvement of the status of this valuable and yet officially unappreciated member of the military service.

The Presidio General Hospital.

COL. ALFRED C. GIRARD, U. S. A., presented an exhaustive report of the U. S. A. General Hospital at the Presidio of San Francisco, Cal., for the years 1901-02. The report dealt with the general administration, the medical, surgical, bacteriological, eye, ear, nose and throat and the *x*-ray work. The total number of patients was 4,551, with a mortality of 92. The surgical cases numbered 728, of which 106 were for hernia, 58 for gunshot wounds, 35 for varicocele, 27 each for appendicitis and tumors, 10 each for bolo wounds and hepatic abscess. The report was accompanied by valuable appendices on liver abscesses, and the mosquitoes of the Philippines.

Surgeons General of the Army.

MAJOR JAMES EVELYN PILCHER, U. S. V., presented a series of biographical sketches of the surgeons general of the army, from the Revolution to the close of hostilities in the Philippines, illustrated by a complete series of portraits.

Instruction of Hospital Corps.

CAPT. FREDERICK P. REYNOLDS, U. S A., detailed the following principles on which the work of the U. S. A. Hospital Corps Company of Instruction should be based: 1. To at once impart a thorough knowledge of discipline in the same way and by much the same methods as is imparted in the line of the Army, with which the hospital corps is always serving; 2, to teach men the principles of order and neatness, both as regards themselves and their personal equipment, and also to familiarize them with the departments of a hospital and the articles with which they work; 3, after this, to impart to each man a knowledge, as far as his mental capacity will permit, of practical nursing, of preparation of diets for the sick, of first-aid and transportation of the wounded, and of ambulance driving and care of animals; 4, to teach them to care for themselves and the equipment entrusted to them in field service, and to be familiar with the usual duties of hospital corps men on the march, in camp, and during an engagement; 5, to instruct in clerical work, materia medica and pharmacy those who have aptitude for such work.

Retirement and Pensions.

MEDICAL DIRECTOR JOHN C. WISE, U. S. N., premised that the medical officers of the United States Navy are more directly responsible than anyone else for the ultimate incidence of our vast pension appropriation, and urged the highest care in diagnosis and record with especial attention to the question of incurrence if disability in the line of duty.

Prevention of the Spread of Infectious Diseases on Board Ship.

SURGEON HENRY G. BEYER, U. S. N., confined himself to the consideration of measles, an affection of singular importance in military and naval service, and recognized that the chief danger of infection in this and allied diseases lay first with the patient, and only secondarily with the persons and things with which he had been brought in contact. The author's practice was, the disease having been diagnosed, to sterilize by steam the patient's clothes, using bichlorid for disinfecting the shoes. The patient then had a thorough scrubbing with soap and warm water, and a complete sponging with bicholorid 1 to 2,000, and was put to bed wrapped in a sheet moistened with the same solution. The bichlorid bath was

repeated thrice daily during the height of the eruption and twice a day thereafter. The mouth and nose were frequently cleansed with normal salt solution containing a minute quantity of carbolic acid or bichlorid. All excretions were immediately disinfected and complications promptly treated. By the use of these precautions the author believed it possible readily to control the spread of the disease.

Antimalaria Work.

LIEUT. F. F. RUSSELL, U. S. A., summarized the result of two seasons of work against malaria made at Ft. Washington, Md., 13 miles below Washington. The use of petroleum on the stagnant breeding pools in the neighborhood was immediately beneficial, resulting in the first year in the diminution of the percentage of malarial cases from 19.53 to 8.63; and this percentage was reduced the following year to 4.18. The use of the oil was a measure of temporary resort only, and the author considered that a portion, at least, of the good results, was due to the establishment of a general drainage system.

Tuberculosis at Fort Stanton.

SURGEON PAUL M. CARRINGTON, U. S. P. H. and M.-H. Service, described the treatment of tuberculosis at Fort Stanton. He is a sturdy advocate of tent-dwelling for the consumptive. The spread of infection is controlled by the use of spit cups and periodical disinfection of apartments. While an advocate of exercise under favorable conditions the author believes that the advice to "go West and rough it on a ranch" is responsible for many unnecessary deaths.

Medical Treatment of Appendicitis.

LIEUT. E. CASTELLI of the Italian Army believes that the appendix must be considered as a tubular ganglion, receiving germs either from the blood or the lymphatics, by which appendicitis may become a complication in scarlet fever, pneumonia, erysipelas, parotitis, etc. The author is opposed to treatment by opium or local ice applications, but resorts to preliminary treatment by salicylate of sodium as a cholagogue and antithermic. Three hours later he administers calomel as an antiseptic, cholagogue, laxative diuretic and pancreatic stimulant. He controls the pain by warm baths and hot saline solution enemata. The bacterial cause of the trouble, residing in the blood, is treated by subcutaneous injection of a dilute carbolic acid solution.

Latent Malarial Infection.

LIEUT. CHARLES F. CRAIG, U. S. A., described the pathology of malarial infection, which had not been manifested by symptoms, and in which blood examination did not necessarily show the presence of malarial parasites. His observations were based on autopsy findings. He found that the changes were confined almost entirely to the spleen, and consisted chiefly in an engorgement of the splenic sinuses with red cells and leucocytes, the presence of infected red cells and of phagocytes and melaniferous leucocytes, increase in the cells and the splenic pulp with more or less degeneration and karyokinesis and pigmentation of the organ confined to the edges of the Malpighian corpuscles and the splenic sinuses and trabeculæ. These facts bear out the time-honored theory that the spleen is the seat of malarial infection.

Early Differential Diagnosis of Typhoid Fever.

MAJOR FREDERICK SMITH, D.S.C., R.A.M.C., was awarded the Enno Sander Prize for his essay on this subject. He considered his subject under the following heads: Introductory; subjective early symptoms; objective symptoms; temperature as an aid in the diagnosis; typhus and relapsing fevers; tuberculosis, respiratory diseases and influenza, meningitis, septicemia, puerperal fever, pyemia, endocarditis, pericarditis, glanders; gastroenteritis, pericecal inflammation, dysentery; febricula; Malta fever; malarial fever; plague and other diseases mistaken for typhoid, and chemical reactions and microscopic methods in relation to the earliest stages of typhoid. He concludes that, in the field, the medical officer must rely mainly on his clinical acumen and summarizes his studies in that direction as follows: 1, There is scarcely any disease accompanied by fever which has not been at times mistaken for typhoid fever; 2, a good many cases are wrongly diagnosed owing to carelessness or to want of knowledge; 3, the disorders most liable to be confounded with typhoid fever are: Typhus fever, tuberculosis, pneumonia, influenza, febricula, or unnamed continued fever, Malta fever, malarial fever and paratyphoid; 4, it is frequently impossible by non-bacteriologic methods to differentiate between typhoid and the diseases named above in four days or even a week and more; 5, our safety, from a public health point of view, lies in regarding all doubtful cases as typhoid until they have been proven to be something else, and 6, the anomalous cases are more numerous and the difficulties in the way of diagnosis greater, in military than in civil life.

History, Cause and Mode of Transmission of Yellow Fever.

LIEUT. JAMES CARROLL, U. S. A., presented an encyclopedic paper tracing yellow fever from its earliest historical appearance in Barbadoes in 1647 to the decline of the disease in Cuba in 1902. The author concludes that yellow fever is contracted only through the bite of infected mosquitoes twelve or more days after feeding on the patient in the earlier period of the disease. Experimentally, the disease can be produced by subcutaneous injection of blood or even of infiltrated blood serum of a patient, provided the material can be obtained sufficiently early in the attack.

The Treatment of Yellow Fever in Havana.

COL. WILLIAM C. GORGAS, U. S. A., emphasized the desirability of receiving the patient during the first three days of the attack and of keeping him in the recumbent position absolutely without exertion. Food was prohibited during the active stage and milk was given when the temperature subsided unless contraindicated. Water and cracked ice were given ad libitum. Cathartics were employed as needed. Phenacetin was exhibited for headache and muscular pain. Saline enemata and local applications to the back were given for urinary suppression or diminution. The convulsions were due to toxemia rather than to uremia as had been previously supposed. Gastric hemorrhage was treated by cracked ice and rest, without astringents. This treatment, as compared to the use of drugs as employed by the Spanish physicians, was far more successful, as the mortality of the American Hospital was 12 per cent. less than that under the Spanish treatment.

Spinal Anesthesia in Military Surgery.

LIEUT.-COLONEL AUGUSTIN AGUIRRE of the Mexican Army presented an interesting report of the subarachnoid injection of hydrochlorid of cocain, according to the method of Tuffier, for which he claimed the following advantages: Ease of application; the surgeon is his own anesthetist; speedy action; absolute safety and a small, easily carried and readily sterilized armamentarium. The author reported 210 cases in which the drug had been employed.

Tropical Abscess of the Liver.

LIEUT. E. W. PINKHAM, late U. S. A., reported sixteen cases of hepatic abscess with seven recoveries, the high mortality being due to failure to recognize the condition sufficiently early. He observed that the so-called abscesses of the liver are not really abscesses nor are their contents pus; they are rather areas of necroses, liquefaction of liver tissues and are made up of liver cells in all stages of degeneration and disintegration, free fat globules, more or less of blood corpuscles, and serum. He commented on the freedom with which the liver may be examined without dangerous hemorrhage, and objected strongly to evacuation and drainage by the trocar or cannula, urging free incision.

Anterior Dislocation of the Shoulder.

ASST.-SURGEON GENERAL G. TULLY VAUGHAN, U. S. P. H. and M.-H. S., recommends the following methods, in the order given, of the treatment of anterior dislocation of the shoulder: Direct reposition; extension and counter-extension; Kocher's method; and arthrotomy. He related a case in which all were successively employed, free opening finally showing that reduction had been provided by a detached greater tuberosity; reduction was then easily affected by pressure in the axilla with adduction of the arm.

The Interoceanic Canal.

The following resolutions, presented by Lieutenant-Colonel J. K. Weaver, N. G., Pa., were unanimously adopted:

WHEREAS, It is well known that the previous excavations for an Isthmian canal have been attended with a large amount of illness and a heavy mortality, due mainly to malaria and yellow fever; and

WHEREAS, Recent discoveries as to the cause of these diseases have enabled medical officers to control their ravages to a marked degree; and

WHEREAS, The success which has crowned medical efforts in Cuba, in abolishing yellow fever in the island, almost banishing malaria from Havana and entirely eradicating malaria as a factor of the death rate of the Army in Cuba, is conclusive evidence that if proper hygienic precautions are taken at Panama and other situations, along the route of the projected interoceanic canal, the death rate of the past can be diminished and practically made to disappear; therefore, be it

Resolved, That, in the judgment of the Association of Military Surgeons of the United States, in annual meeting assembled, the amplest power should be given to the medical officers in charge of the sanitation of the canal, and that, to attain this end, the medical officer in charge should be a member of the commission which the President of the United States is authorized to appoint to conduct the affairs of the canal; and be it further

Resolved, That the Secretary of the Association is instructed to forward this preamble and resolutions, properly attested, to the President of the United States.

Reorganization.

The Committee on Incorporation,, through its chairman, Major William C. Borden, U. S. A., announced that the association was incorporated by Act of Congress, approved Jan. 30, 1903. The association proceeded to reorganize under the law.

Election of Officers.

The following officers were elected for the ensuing year: President, Medical Director John C. Wise, U. S. Navy; vice-presidents, Surgeon-General Walter Wyman, U. S. P. H. and M.-H. S.; Major Albert H. Briggs, surgeon, N. G., N. Y.; Brigadier-General Robert M. O'Reilly, surgeon-general, U. S. Army; secretary and editor, Major James Evelyn Pilcher, U. S. Army, and treasurer, Major Herbert A. Arnold, surgeon, N. G., Pa. St. Louis was selected as the place of meeting for 1904.

Resolutions.

After the induction of the new officers, appreciative resolutions were unanimously adopted in acknowledgment of the courtesies of the citizens of Boston, including the Medical Library Association, Surgeon-General Blood, Captain Myles Standish, Lieutenant F. L. Gibson, Dr. Henry O. Marcy and the host of hospitable and generous people who had contributed so freely to the entertainment of the association.

NEW YORK STATE MEDICAL ASSOCIATION.

Nineteenth Annual Meeting of the Fifth District Branch, held in New York City, May 19, 1903.

The President, Parker Syms, M.D., in the Chair.

Symposium on Malaria.

DR. W. N. BERKELEY opened this symposium with a paper in which he described the three species of anopheles mosquito, and insisted that drainage was the only permanently effective remedy against these pests.

Laboratory Diagnosis and Life Cycle of the Parasite of Malaria.

DR. W. T. KLEIN described the various stages observed in the malarial plasmodium during the endogenous cycle in the human being, and said that the plasmodium was very rarely found free in the blood plasma. The breaking up of the segmenting body and the liberation of the spores were coincident with the rigor. The cycle was completed approximately in forty-eight hours in the tertian variety. The quartan ring was slightly smaller than the tertian, and its pigment granules were smaller and more numerous. Its cycle was completed in 72 hours. The estivo-autumnal form was also smaller and more delicate than the tertian, and it presented two types, one having a cycle of 24, and another a cycle of 48 hours. The parasite of malaria was transferred to man by the bite of the mosquito, and, if the inoculation were successful, which was by no means always the case, malaria usually developed in eight or ten days. Either a dry or a fresh specimen of blood could be made use of for diagnostic purposes, but, whenever possible, it should be taken about eight hours after the chill, because just prior to the occurrence of the chill the malarial plasmodia showed a tendency to retire from the peripheral circulation to the internal organs. A one-twelfth inch oil immersion lens was required for the examination, and a large experience in this field of work had taught him that preference should be given to Goldhorn's staining method, not only because the fixing and staining process could be done in about one minute, but because the chromatin granules were so brilliantly stained as to materially aid in the diagnosis. A marked diminution in the number of red blood corpuscles and in the hemoglobin was a constant occurrence in malaria, and an absence of leucocytosis was likewise a characteristic feature. This was an important point in the differential diagnosis of malaria.

The Concurrence of Anopheles Mosquitoes and Malaria.

MR. HENRY CLAY WEEKS, engineer in economics, discussed this topic. He deplored the prevalent tendency of the people of a malarial region to conceal the true facts, and their dread of taking an active interest in the work of exterminating the disease lest by so doing the locality might get a bad name. It was far better for all concerned to face the truth, and take steps toward the banishment of such a public disgrace. He called attention to a fact often overlooked even by medical men, i. e., that the larvæ of the anopheles are found much later in the season than those of the ordinary mosquito.

Clinical Diagnosis and Treatment of Malaria.

DR. ALEXANDER LAMBERT discussed this phase of the subject. He pointed out that while there were occasional mild cases of malaria in which the attacks only lasted four to six hours, true malaria was generally distinguished from other diseases characterized by chills by the fact that ten or twelve hours were required for the complete cycle. Another distinguishing point was that in malaria, as seen in this part of the world, the pulse did not rise in proportion to the temperature, a temperature of 104 F. often being associated with a pulse rate of less than 100. He quoted Captain Delaney of Calcutta, who had had a very large experience with malaria in that region, as saying that a justifiable diagnosis of malaria was possible in over 90 per cent. of the cases by means of a differential count of the leucocytes. If the large mononuclear leucocytes, i. e., those mononuclear cells which were as large as the polynuclear ones, constituted over 12 per cent., one was warranted in making the diagnosis of malaria. In differentiating malaria from tuberculosis, it should be remembered that in the early stages of the latter disease the temperature usually ranged between 97 and 100 F. In sepsis the febrile and sweating stages were of comparatively short duration and recurred at irregular intervals. In cholelithiasis there was a remittent form. In yellow fever there was a falling pulse, with a stationary or rising temperature. It was often very difficult to distinguish between estivo-autumnal malaria and typhoid fever, but the temperature curve, the history and the other symptoms would usually suffice for such differentiation. The enlargement of the spleen did not occur as early in typhoid as in malaria. The diazo-reaction in the urine in the early days of typhoid was often of assistance. In this latitude many mistakes in diagnosis would be avoided if it were made the rule to exclude malaria, unless the plasmodium were found in the blood. The speaker said that, in his experience, Manson's method of treatment had proved uniformly successful. It is carried out as follows: Five grains of quinin are given every four hours until the temperature returned to the normal, and then three grains should be given three times daily. At the same time the patient should take daily a drink made by cutting up the rind, pulp and seeds of a lemon, placing them in one quart of cold water and boiling this down to one pint. This drink should be taken daily for four months. It should be strained before taking, and could be sweetened as desired. After three weeks the patient should take a calomel purge, and then three grains of quinin three times daily for one week. This week of medication should be repeated at the end of the month, and at intervals of a month thereafter for four or five months. The hydrochlorate of quinin contained more of the alkaloid and was more soluble than the ordinary sulphate of quinin.

DR. FRANCIS P. KINNICUTT did not think that clinical experience had proved this treatment of Manson to be so effective

as that of Ross, which was as follows: Ten grains of quinin are given every two hours for the first fortnight, 15 grains daily for the next fortnight, ten grains for the second month, 5 grains for the third month. The dose should be increased from five to ten grains at first twice a week, and later at weekly intervals. The treatment should be invariably continued for four months, even though no relapse occurred. Where a person was unavoidably exposed to infection, an excellent prophylactic treatment consisted in taking five grains of quinin daily, increasing the dose to ten grains twice a week.

DR. DAVID P. AUSTIN called attention to the strong tendency to relapses at intervals of a week for the first month, as well as to the value of combining quinin with calomel and capsicum.

DR. W. I. COCKE of Port Washington, L. I., described his favorable experience with nuclein in the treatment of malaria.

Officers Elected.

The following officers were elected: President, Dr. J. C. Bierwirth, Brooklyn; vice-president, Dr. Milton C. Conner, Middletown; secretary, Dr. E. V. Hubbard, New York City; treasurer, Dr. Henry Dodin, New York City.

GERMAN CONGRESS OF SURGERY.

The thirty-second annual congress of German surgeons was held at Berlin, June 3 to 6, and a number of interesting communications were presented. Prof. G. Gaertner, Vienna, inventor of the "tonometer," exhibited a somewhat similar instrument for watching the pulse during narcosis. It is worn on the wrist like a bracelet, and an index registers the pulse on a large dial. Narath, Utrecht, presented a "gastrophor," a device to aid in operations on the stomach and to dispense with an assistant. An exposition of surgical appliances contained the new instruments, nearly all of which seem to have been described in THE JOURNAL during the last year. Kraske, Freiburg, expatiated on the

Dangers of Raising the Pelvis

in operating, and cited several instances from his own experience in which the Trendelenburg position had entailed fatal consequences. Paralysis of the anterior tibial nerve and emphysema of the abdominal walls are not serious and can be avoided. He refers more particularly to the disturbances in the circulation in obese subjects. In two patients of this group, with signs of myocarditis, an operation on the bladder under ether was followed by heart failure the next or the fifth day. He thinks that this fatal result was due to the increased blood pressure and consequent dilatation of the heart. In three cases occlusion of the intestines followed a laparotomy with the pelvis raised. One patient spontaneously recovered after five days of ileus. In another, a still more tempestuous case, the entire omentum was found rolled up under the liver, the colon adherent to it, and completely occluded. The conditions were relieved by a laparotomy, but the patient soon succumbed. Schauta has reported two cases of torsion of the small intestine in consequence of the Trendelenburg position, and insists that the viscera should all be carefully restored to their normal places before closing the abdomen. In a third case the raising of the pelvis caused severe post-operative hematemesis. Trendelenburg, Leipsic, in the discussion that followed, called attention to still another danger, suffocation from aspiration of vomited matters when the stomach is not empty as the operation is commenced. He has lost a patient from this cause. König, Berlin, warned against the slanting position in operating on intraperitoneal abscesses for fear that some of the contents may escape into the upper parts of the abdominal cavity.

Küttner, Tübingen, proclaimed that he had saved laboratory animals, otherwise doomed, by intravenous injection of a saturated

Oxygenated Saline Solution,

and exhibited an apparatus he had devised for the purpose. He found inhalation of oxygen under pressure an effective measure, especially when combined with the intravenous injections.

Massage in Recent Fractures.

Jordan, Heidelberg, has found in 100 cases that early massage and application of a splint after each massaging resulted in more rapid and better functional and anatomic cures than he had ever attained by other measures. Even when immobilization is necessary, it should always be preceded by massage, and be restricted to the minimum.

Cancer in Digestive Tract.

Petersen, Heidelberg, affirmed that cancer in the rectum has a tendency to bore into the depths, while gastric cancer spreads by predilection on the mucosa, and is shallower. He also claims that some of the cancer cells are destroyed in the lymph glands. He makes a practice of extensive resection of the stomach but does not think it necessary to remove all the glands in the region. In 30 cases of resection of the stomach at Heidelberg, on account of cancer, 7 of the 18 who survived the intervention are still alive.

Paraffin Prothesis for Hernias.

Eckstein, Berlin, advocated treating inguinal and umbilical hernia by this means, but Gersuny, the inventor of the measure, emphatically denounced this application of it. The hernia is not cured, but merely concealed behind the paraffin. Others, however, have been successful with it, injecting paraffin with a melting point of 40 C. into the hernia sac after reduction of its contents.

Operative Treatment of Epilepsy.

Kümmell, Hamburg, stated that he had treated 30 cases of epilepsy by Kocher's method of draining the ventricle. The epilepsy vanished as long as the drainage continued, but returned as soon as it was suspended.

Esthetic Ablation of Lymphomata in Neck.

Dollinger, Budapest, has been very successful in removing these tumors without a scar or recurrence. He works through an incision in the edge of the hair, and has even succeeded in removing supraclavicular ganglia by this route. Out of 128 operations of this kind there was slight post-operative suppuration in only 21, and it was not tuberculous, and healed as soon as a small drain was introduced at a counter-opening. There has been recurrence in only 2 of the entire number.

Suture of the Heart.

Four surgeons reported direct suture of the heart, one having done it in 3 cases. All of the 6 patients recovered except 2, and Rehn mentioned that his patient operated on six years ago is in good health to-day.

Treatment of Cavernous Angioma with Magnesium Darts.

Payr, Gratz, reported that a cavernous angioma on the cheek was very much reduced in size by his method of introducing magnesium darts. He inserted 42 in six sittings. The little darts are soon absorbed, but they induce the formation of compact connective tissue with thrombosis and obliteration of the spaces. The vascular tumor is thus reduced to an insignificant size, or its extirpation is rendered easy without fear of hemorrhage. He has thus treated 8 or 9 cases with complete success.

Recovery After Impalement.

Franke, Brunswick, described a remarkable case of complete transverse perforation of the thorax. A woman fell from a height on a broom handle, which entered at the right axilla and emerged in the other. He saw the patient soon after the accident, and found considerable emphysema of the subcutaneous tissue, progressive dyspnea, a wound in the right axilla and a very tender point in the left axilla, the region which seemed to be the starting point for the emphysema. He had the patient taken to his ward at once and made an incision in the left axilla through which he could palpate with his fingers a perforation of the thorax wall in the third interspace. The lung had evidently retracted from the thorax wall, and in order to avoid pneumothorax he tamponed the wound at once. He then inspected the right axilla, and found here likewise a perforation of the third interspace, and he tamponed this also. The patient had quite recovered in fifteen days. He adds that the blood stains on the broom handle corresponded exactly with the transverse diameter of the thorax. It must have pushed back the heart and lungs without injuring them.

The *Semaine Médicale* of June 10 and 17 contains an elaborate report of the congress. Most of our German exchanges are publishing the "collective report" in installments.

MONTANA MEDICAL ASSOCIATION.

Twenty-fourth Annual Meeting, held at Helena, June 17 and 18, 1903.

Dr. T. J. McKenzie, Anaconda, President, in the Chair.

An address of welcome was delivered by Mayor Frank J. Edwards of Helena, which was fittingly responded to by the president of the association. After roll-call and the admission of sixteen new members, a good scientific program was taken up and discussed.

The following officers were elected for the ensuing year: President, Dr. Louis Bernheim, Butte; vice-presidents, Drs. Donald Campbell Butte; George H. Barbour, Helena, and E. F. Conyngham, Phillipsburg; secretary, Dr. Ben C. Brooke, Helena; treasurer, Dr. Isadore D. Freund, Butte; councilors, Drs. Thomas J. Murray, Butte; G. T. McCullough, Missoula; T. J. McKenzie, Anaconda; Ernest Crutcher, Great Falls; Charles F. Hopkins, Chinook; W. B. Kingsbury, Dillon; William C. Riddell, Helena; Alexander D. McDonald, Kalispell; Robert D. Dalton, Livingston, and James Chapple, Billings. The next meeting of the association will be held at Butte on the second Wednesday and Thursday of May, 1904.

Dr. John A. Donovan, Butte, introduced the following resolution, which was adopted:

Resolved, That the Medical Association of Montana approves the plan of examination of eyes and ears of all school children as recommended and practiced by the Illinois State Board of Health and approved by the American Medical Association and many other organizations. That we recommend said plan to our state board of health and board of education for their approval and action. That hereafter every child will be carefully examined by the teacher at least once a year and records made according to the prescribed simple forms printed for this purpose. That the parents of any child who is found defective in sight or hearing be notified, that said parents may act as they see fit.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the disease seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Sulpho-Carbolate of Zinc in Cholera Infantum.

Dr. W. F. Waugh, in the July number of *Alkaloidal Clinic,* recommends sulphocarbolate of zinc in infantile summer diarrhea and in cholera infantum. His routine treatment is to clear out the bowels with castor oil, calomel, mercury and chalk, aromatic rhubarb, lavage or colonic flushing as seems best in each case. This is followed by the zinc salts every hour in 1/6 to 2 gr. doses. It is given in solution or powder form, and, in cases of decided irritability, combined with pepsin and bismuth. When there is extreme acidity marked by rectal excoriation, sulphocarbolate of sodium is substituted.

Diarrhea.

The *Journ. of Tropical Med.* quotes the following combinations in the treatment of diarrhea:

℞.	Tinct. camphoræ	3i	4
	Tinct. capsici	3ss	2
	Tinct. lavendulæ co.	3ii	8
	Spts. vini gallici q. s. ad	℥ii	60

M. Sig.: One teaspoonful every two or three hours.

In the treatment of chronic summer diarrhea the following combinations are recommended:

℞.	Bismuthi subgal.	gr. xxiv	1 60
	Pulv. opii	gr. ss	03
	Pepsini pulv.	gr. vi	40

M. Ft. chart. No. xii. Sig.: One every four hours, alternating with the following:

℞.	Hydrarg. chloridi mitis	gr. ss	03
	Cerii oxalatis	gr. ii	12
	Sacch. albi q. s.		

M. Ft. chart. No. xii. Sig.: One every four hours.

Pustular Acne of the Face.

According to Leredde, in an abstract in *Amer. Med.,* an acne developing on a sensitive skin, as in women, should not be confounded with an acne developing on a thick skin, which is but slightly sensitive, when the treatment is being considered. He regards sulphur as the best remedy, but its action depends not so much on any special property of the sulphur as on the excipient combined with it. He, therefore, makes two classifications of excipients: First, those that tend to congest the skin, obliterate the glands, and prevent cutaneous perspiration. (In this class he includes the fats.) Second, the agents which decongest the skin and facilitate cutaneous perspiration, such as powders and pastes. The latter are employed when the skin is sensitive.

The following combinations may be of service:

℞.	Sulphuris precip.	3v	20
	Saponis nigri	3iiss	10
	Acidi pyrogallici	3i	4
	Zinci oxidi	℥i	30
	Liq. petrolati	℥iii	90

M. Sig.: Apply locally at night.

The parts should be washed thoroughly with salicylated soap before applying the ointment. If the skin is hard, the paste may be left on over night and removed the next morning. In women the paste should be removed at the end of two hours. According to the author, larger amounts of the sulphur can be used, and are borne better when prescribed as a paste than when prescribed with simple fat.

When the skin is not sensitive the following ointment may be employed:

℞.	Sulphuris precip.	3i	4
	Hydrarg. chloridi mitis	3ss	2
	Lanolini	3v	20
	Liq. petrolati	℥iiss	75

M. Ft. unguentum. Sig.: To be applied locally.

The general condition of the patient must be carefully inquired into and properly corrected if possible. Especially must gastric disturbance be avoided.

Neurasthenia.

The following combinations are of value in the treatment of neurasthenia:

℞.	Ferri glycerophosphatis		
	Sodii glycerophosphatis, āā	3i	4
	Berberinæ phos.	gr. xii	75

M. Ft. capsulæ No. xxiv. Sig.: One capsule before each meal.

When pronounced anemia is present the following combination containing arsenic and iron should be prescribed:

℞.	Acidi arsenosi	gr. 2/3	04
	Ferri sulphatis	3i	4
	Ext. nucis vomicæ	gr. vi	40
	Potassii carbonatis	3i	4

M. Ft. capsulæ No. xxiv.

The lecithin preparations, made from the yolk of the egg, are regarded by some as exerting specific action in this disorder. It may be prescribed in one of the following forms:

℞.	Glycerol lecithin	℥ii	60

Sig.: One-half teaspoonful after each meal, gradually increased to one teaspoonful three times a day: or;

℞.	Pil. ovo-lecithin ana	gr. iii	20

No. xxiv. Sig.: One pill three times a day after each meal.

Phosphorus combined with zinc makes a good combination to be used in some cases:

℞.	Phosphori	gr. ss	03
	Zinci valerianatis	3i	4

M. Ft. pil. No. xxx. Sig.: One pill after each meal. If the patient suffers from insomnia the following should be given at bedtime:

℞.	Sodii bromidi	3v	20
	Tinct. hyoscyami	3iv	15
	Elix. simplicis q. s. ad	℥ii	60

M. Sig.: One teaspoonful at bedtime, for sleep, and repeat in one hour if necessary.

It must not be forgotten that autointoxication is present as a causative or aiding factor in many of these neurasthenic cases. Consequently the alimentary tract must receive proper

attention by keeping the bowels freely open, either with saline purgatives or small and repeated doses of calomel. Intestinal antiseptics are valuable, such as salol, thymol or creosote in small doses. Hydrotherapy, prescribed to suit the individual case, is indicated. It may be administered in the form of baths, douches or sprays.

Medicolegal.

Liability of Company for Malpractice After Fraud.—The Court of Civil Appeals of Texas holds, in Jones vs. Railway Company, an action brought to recover for personal injuries received by the wife of the party suing, that oral evidence would be admissible to show that, as an inducement for the party suing to execute a release to the company, the latter undertook to have his wife further treated by its physicians and to pay her board bill. If the company furnished medical treatment to the wife in consideration of the execution of the release, it would be liable for unskilful treatment, although the release should be set aside on account of fraud in its procurement.

Five Thousand Dollars for Injury to Spine.—The case of Sweeney vs. The New York Central & Hudson River Railroad Company was brought by a young woman who was at the time of the trial 22 years of age to recover for alleged permanent injuries to her spine. The extent of her injuries was a sharply contested point. Several witnesses beside the woman herself, and including two physicians, were sworn to sustain the contention that such injuries were very severe. On the other hand, evidence was given in behalf of the company to the effect that her claims in reference thereto were greatly exaggerated. Under these circumstances the Fourth Appellate Division of the Supreme Court of New York does not feel that the evidence warranted it in disturbing a verdict in her favor or feel willing to say that one for five thousand dollars was excessive.

Cases of Privilege.—The Second Appellate Division of the Supreme Court of New York says, in the case of Duggan vs. Phelps, that it is held that what is seen by a physician in looking at the patient is within the privilege (Grattan vs. Metropolitan Life Ins. Co., 92 N. Y., 274); that it is not necessary that the physician should be employed by the patient, or that there should be a contract relation between them (Renihan vs. Dennin, 103 N. Y., 573); that the party suing, by calling his physician to testify as to his disease and its treatment, does not waive his objection to the evidence of other physicians who had treated him at other periods (Hope vs. Troy & Lansingburgh Railroad Company, 40 Hun., 438, affirmed in 110 N. Y., 643); and that although a patient gives evidence as to his condition both before his entrance to a hospital and after he leaves it, he does not waive the privilege as to a physician who treated him in that interim (Barker vs. Cunard Steamship Company, 91 Hun., 495, affirmed in 157 N. Y., 693). In the present case, the party suing for damages for personal injuries testified that after the accident he was taken in an ambulance to a hospital; that he left there the next day, and was thereafter treated at home by his own physician, who testified in detail as to the injuries and the treatment. The other party called the ambulance surgeon, who had charge of the party suing and treated him in the hospital. The court holds that the calling of his own physician as a witness was not a waiver of privilege as to the ambulance surgeon. It distinguishes the case from Green vs. Metropolitan Street Railway Company (171 N. Y., 201, page 45 of THE JOURNAL of July 5, 1902), and Griffiths vs. same company (171 N. Y., 106, page 103 of THE JOURNAL of July 12, 1902), by the fact that the ambulance surgeon testified that he had charge of the party suing, and recalled what he did for him, and that he treated him after he came to the hospital, after which he was asked to state his condition at the time that he "first saw him, that he treated him." It says he was therefore asked to speak in the relation of physician to patient.

What Deemed a Bodily Infirmity—Pension as Evidence.—The United States Circuit Court of Appeals, Third Circuit, holds, in the case of Black vs. the Travelers' Insurance Company, that an infirmity of the body, as the term implies, is something that materially impairs the bodily powers. In a case where this is clearly made out, it is no doubt the duty of the court to take the question from the jury and dispose of it; but ordinarily it is for them to pass on. For example, in this case an applicant for insurance warranted that he had never had "any bodily or mental infirmity." It was proved, however, that while a soldier in the Civil War he received a gunshot wound in the back of the head, by which the external table of the skull was fractured, a piece about half an inch square taken out, and a slight depression of the inner table produced. On the strength of this, in December, 1868, he was granted a pension by the United States government of $8 a month, which was increased to $12 in July, 1886, and in December, 1889, to $14 on account of alleged resulting vertigo and impaired vision. But, aside from the pension record, there was nothing to show that the wound, which healed over quite speedily, materially affected the general health of the insured, which, according to the testimony of several witnesses, was uniformly good; and the court holds that the question of whether the condition produced by the wound was a bodily infirmity within the warranty, and constituted a breach of it, should have been left to the jury. In other words, it holds that an injury or infirmity, the existence of which constitutes a breach of such a warranty, must be such as amounts to an actual inroad on the physical health or condition of the insured, and that this, as a rule, is a question for the jury. The mere reception of a pension, it holds, did not establish that he was affected with a bodily infirmity, but only that it had been so represented by him to the pension department. However far in that direction this may have gone it was not conclusive on the question of the existence of a disability regardless of the other proofs. Even on the most disadvantageous showing it amounted to no more than a declaration or statement by the insured, which, like any other, it was for the jury to consider and pass on along with the other evidence.

Prescriptions Under Local Option Law.—By the Texas constitution the legislature is required to pass a "local option law," which is restricted to a prohibition of the sale of intoxicants. Article 405 of the penal code, in substance, prescribes the punishment against all parties who undertake to give prescriptions in local option territory, except regular, practicing physicians, and against them if they should give prescriptions without a personal examination of the applicant, which personal examination must disclose the fact that the applicant is sick. But the Court of Criminal Appeals of Texas holds, in Stephen vs. State, that the legislature has no authority to punish a party for giving a prescription to himself. No more could he be punished for giving a prescription to a third party. The legislature has not been authorized by the constitution to prohibit the giving of prescriptions. This is not a sale, nor can it be tortured into a sale. It may be admitted that it contemplates the purchase of the intoxicant, but it is not a purchase or a sale. The information in this case did not charge a sale. It simply charged the giving of a prescription for the purpose of obtaining intoxicants. That a physician may be guilty of violating the local option law by means of giving a prescription may be conceded, though it would not be for giving a prescription, but for bringing about the illegal sale. Cases can be well imagined and readily conceived where a physician, for the purpose of assisting the seller in making the sale, would become particeps criminis in the sale. Or if the physician, without connivance or complicity of the seller, should, by means of a prescription, or any other means, use the seller as an innocent instrument in violating the local option law in the sale, then he (the giver of the prescription) would be guilty under the statute. In such instances he would, were the case a felony, bear the relation of an accomplice to the crime, but, being a misdemeanor, he would be a principal. But there must be a sale alleged and proved in order to make a violation of the local option law. The court adds that it is not discussing what it would take to constitute a sale, but only holds that a party can not be convicted of violating the local

option law until he has been instrumental criminally in bringing about a sale of the intoxicants within the prohibited territory. This must be alleged. And it holds that the information in this case did not charge an offense.

Medical Record, New York.

June 27.

1 *On Septic Thrombosis of the Roots of the Portal Vein in Appendicitis and on Pylephlebitis, Together with Some Remarks on "Peritoneal Sepsis." Arpad G. Gerster.
2 The Late Dr. T. Gaillard Thomas. Henry D. Nicoll.
3 *A New Blood Stain. George L. Laporte.
4 *Feeding of Older Infants and Children. W. M. Hartshorn.

1.—See abstract in THE JOURNAL, xl, p. 1595.

3. **A New Blood Stain.**—Laporte describes his method of staining as follows:

First, make a .5 per cent. solution of Jenner's powder (Gruebler's) in methylic alcohol (Merck's highest purity). Do not filter this solution. Second, make a solution of one part Unna's polychrome methylene-blue solution (Gruebler's) to 150 parts of distilled water (about 2 drops to 15 c.c.). Then proceed as follows: Take the cover-class specimen in a Cornet forceps, drop on it 5 drops of Jenner stain, allow this to act one minute, then without removing the Jenner stain, pour on 10 drops of the dilute polychrome methylene-blue solution. Agitate the forceps so as to produce a thorough mixing of both solutions on the cover-glass. Allow the combined stain to act five minutes longer. Then wash off with distilled water and allow some of this to rest on the cover-glass about one minute longer with occasional agitation of the forceps. At the end of this time dip the specimen rapidly into a very dilute acetic acid solution (about 1 drop of 50 per cent. acetic acid to 10 ounces of water) until it is of a reddish or pinkish color. Rinse again with water and dry in the air. Do not employ heat or filter-paper to dry specimen.

This stains red blood corpuscles a distinct pale rose color. The nuclei of the white as well as of the red cells are of a bright carmine purple and the eosinophile granules are of a bright coppery red, the mastzellen granules of a very deep metachromatic blue. The protoplasm of the large and small lymphocytes is a pale light blue dotted here and there with bright purplish chromatin granules. The network of the blood plates takes the carmine purple chromatin color, the bodies of the blood plates staining a light blue. The body of the malarial parasite is stained blue, its chromatin the same as the nuclei of the white cells, only brighter. Granular degeneration of the red cells appears as fine blue specks in the affected cells. A few minor details must be observed. The specimens should not be fixed in any way and should not be too old. The time given for the Jenner (one minute) and the combined stain (5 minutes) should ordinarily be strictly adhered to. There should always be double the number of drops of dilute polychrome methylene-blue solution to the three or four drops of the Jenner solution. The former should not be added drop by drop, and it is always necessary that the distilled water should be left on the cover glass a minute longer after rinsing off the stain.

4. **Infant Feeding.**—All infants over seven months old, artificially fed in the Nursery and Child's Hospital, New York, during the past four months were given stronger food, especially stale bread, soaked in boiling water until thoroughly softened, when the water was poured off and a cup of milk added, and this boiled for three or four minutes. After being sweetened and cooled sufficiently, it is fed to the baby. At first a teaspoonful once a day is given, but as the infant becomes accustomed to it, the amount is increased so that at the end of ten days it is receiving one to two or three ounces daily. It is given between the regular bottle hours, and never more than half an ounce at a time. If curds appear in the stools or if it disagrees, it is discontinued and castor oil or calomel given. Older children ranging from eighteen months to four years, are all fed on plain bread and milk, with no extra preparation, at least once a day. In the morning they receive farina with milk. At noon boiled rice, with meat broth poured over it, is given to them. For supper they receive plain bread and milk, the older children often receiving some plain jelly spread over their bread. During the fruit season they are allowed an orange or some easily digested fruit at noon. Since they have been giving this extra food for the younger children and infants Hartshorn says they have noticed a marked change in the general appearance of the weight charts for the better.

10 *A Rapid and Easy Method for the Sterilization of Catgut Ligature and Suture Material. John Milton Garratt.

5. **Neuralgia and the Weather.**—Mitchell calls attention to his earlier work, and that of others on the influence of the weather on pain. He remarks that eyestrain is rarely the primary trouble; it may lead up to or exaggerate the force of the attacks, but atmospheric conditions have a potent share in the production of migraine. He has been able at different times to convince himself that certain migraines were due to storms, but not, as a rule, to the summer electric storms, which may, nevertheless, in some hysterical women occasion a general headache, distinct in character from hemicranial attacks. He briefly reports a case and gives the curve showing the monthly average of headaches for seven years in connection with the storm curve, which are strikingly parallel.

7. **Erythropleum.**—This substance, which is the bark of a tree, the Erythroploeum guineense, one of the Leguminosæ and known in Africa as the gidu, mancona, doom, ordeal, casca, saucy and sassy bark. Its mode of action is that of a muscle-poison, acting on the heart earlier because it receives a larger quantity of poisoned blood. On the vagus its action resembles digitalis. It is a vasoconstrictor by acting on the vessels themselves, the vasomotor nerves or on some vasomotor center not contained in the medulla. The respiration is influenced through the pulmonary branches of the vagus. It is an irritant to the nasal mucous membrane, causes vomiting by reason of its solutions possessing the same property, and is diuretic like digitalis. He gives the result of its use clinically where its field of use seems limited to the heart and blood vessels when cardiac disease is not accompanied by dropsy. Its power to slow the heart is rather greater than that of digitalis, but it is more decidedly a gastric irritant. Its vasoconstrictor properties are practically those of digitalis and ergot combined. Its cumulative power is rather less than that of digitalis. The indications for the use of the remedy are those which Withering laid down in the eighteenth century for digitalis, namely, a rapid, low tension pulse with venous congestion. Digitalis, however, is rather more reliable and constant. The use of this remedy should be confined to those cases of fairly competent heart of low vascular tension in which it will show its effects more rapidly and markedly, and to those cases in which digitalis has lost its usefulness or has utterly failed.

8. **Chronic Cyanotic Polycythemia.**—This title is offered as a tentative designation for certain cases recently reported of chronic cyanosis with immense increase in the number of red cells and without cardiac disease. Two cases observed by Hall are reported, in one of which there was a well-defined chronic nephritis with cardiac manifestations. A striking characteristic is the intense cyanosis, giving the lips and tongue the color of ripe Concord grapes. This is somewhat less marked on the hands and still less on the trunk and lower extremities. The dyspnea and palpitation that existed were more striking than in the other cases quoted. He accounts for them by insufficient oxygenation in spite of the increased number of red cells. He thinks it is possible that the increase in the reds is a compensatory process—an attempt to make up the deficiency in oxygen-carrying capacity in individual cells by an increase in their number.

9. **Strychnia.**—Salant has investigated the action of the contents of the large intestine on strychnia, and finds that the simpler methods for the detection of strychnia are more certain in its detection. He accounts for this by the manipulations that are required by the more complex tests and reagents, some of them carrying off portions of the strychnin.

10. **Catgut Sterilization.**—The technic of the method employed by Garratt is given by him as follows:

Have ready one two-quart and one one-quart clean fruit jar for each size of the material used. It is well to have an extra one-quart jar for use in preparing a fresh batch when one on hand is nearly used. The jars must be thoroughly cleaned beforehand and sterilized by boiling or dry heat. The various sizes of catgut can be purchased from any reliable firm dealing in surgical supplies. The sizes found most convenient are 00, 0, 1, 2 and 3. The first three sizes are cut into lengths of about ten inches and used for ligatures and sutures; the last two, 20 inches—used for pedicles, etc. For convenience, a piece of wood 10x3x¼ inches is obtained, and both ends cut to a point and notched at intervals of one-quarter of an inch for catching the ends of the strands. After winding lengthwise, cut the smaller sizes at both ends of the board; the larger at one end only. Three strands of a similar size of the short lengths are placed in an envelope of unglazed paper, a convenient size being 3x1¾ inches. Two strands of a similar size of long lengths are likewise placed in envelope. Seal and mark with an indelible pencil the size number on the outside of the envelope. The number should be made large enough to be plainly seen. It does away with the necessity of putting germ-catchers on the outside of the jar. Envelope and contents of similar size are kept in a two-quart jar until wanted. Sterilization is accomplished by placing 40 or 50 envelopes and contents in a one-quart jar and completely filling it with the following germicidal solution:

Mercuric chlorid	gr. xv	1
Tartaric acid	gr. lxxv	5
Columbian spirits		
Ether, āā	1 pint	473

Put on the cover and screw it down tightly. Allow size 00 to remain in the solution for four hours; size 0, six hours; size 1, eight hours; size 3, twelve hours. After the material has been immersed for the desired time, pour off the solution and drain, then cover envelopes and contents with columbian spirits, screw on the cover, and put away in a clean place until wanted. It is essential that columbian spirits be used. Ethyl alcohol can not take its place, even when the absolute alcohol is used. Columbian spirits is a pure methyl (wood) alcohol practically free from water. It is inexpensive, costing less than the ordinary alcohol. It can be obtained usually at paint stores. It serves to toughen the catgut, acting much the same way as does formalin. In removing the envelopes from the jar use a pair of vulsella forceps kept expressly for this purpose. Thread the needles, then place in recently distilled water. Catgut prepared by this method possesses all the requisites of a good ligature and suture material—strength, pliability, and most important, asepsis. The technic of sterilization is easy to carry out, and it is inexpensive. The very minute quantity of mercuric chlorid remaining in the material overcomes the theoretic objections to its use.

He also remarks on the possibility of infection of cocain solutions, and at the suggestion of Dr. Lee H. Smith makes the solutions up from the dry ingredients, placing them in glass-stoppered one-dram bottles. Just before operation the bottle is filled with a boiling decinormal salt solution. When a bloodless field of operation is desired a 1 to 10,000 solution of adrenalin chlorid is used in its place, the nitroglycerin being omitted. The small bottles are kept in a specimen jar tightly covered until wanted. Since using this solution and the catgut ligature and suture material prepared as above, some 200 operations have been performed without a single suppuration.

17 Report of a Case of Stammering, and Method of Treatment. James M. Brown.

11. **Corrosive Poisoning.**—Long discusses the corrosive poisons, and insists particularly on the chemical basis of their action and the selection of antidotes on the same basis. He would also first insist on the importance of immediate dilution of the poison with a large quantity of water, independent of the nature of the corrosive. This is always practicable.

12. **Appendicostomy (Weir).**—A case of this new operation is reported by Meyer, where a soft rubber tube was passed through the appendix and the bowel regularly flushed with nitrate of silver solutions to treat the ulcerations that existed throughout the entire course of the transverse and ascending colon. Under the treatment the health of the patient has materially improved, though there is still some ulceration in the rectum. She has gained over 15 pounds. The cut end of the appendix is flush with the skin, and there is no granulating surface requiring dressing and no leakage whatever on removal of the tube. There is a little appendicular fistula which acts exactly like the artificial openings made by Kader's and Witzel's methods, contracting rapidly when the tube is removed. Once when flushing was done every other day the tube accidently slipped out, and at the next dressing the appendix was so contracted that it took long and tedious work to reintroduce the tube, thus showing that all that is needed to close the opening is to leave out the tube. If this does not promptly follow, cauterization with Paquelin's cautery will surely accomplish the desired result. Dr. Meyer has little fear of inflammation being set up in the misplaced appendix. It is, as it were, hung up with natural drainage into the cecum. Should it really become inflamed it would be of little consequence as it passes through the abdominal wall in all its length, where it can do no harm, the peritoneal cavity having been long shut off by adhesions. He suggests that this method of using the appendix might be of value in some cases of cancerous stricture. The appendix might be pulled forward to relieve the distended intestinal tract, and stitched into the wound and made use of as indicated. It is probable, of course, that we may rarely meet old patients with an appendix of a caliber sufficiently large to carry out this plan. Still he intends to try it in his next case of obstructive ileus in an old and weakened patient. He thinks the operation is a valuable addition to our operative methods.

13. **Mycosis Vaginae.**—In the patient here described there was intense leucorrhea with vulvar burning and pruritus. Direct examination showed the presence of follicular vulvitis and at a later attack the walls of the vagina were found covered with great numbers of grayish brown, slightly elevated masses, easily detachable, with raw surfaces under them. Examination revealed the presence of fungi, Oidium albicans or thrush fungus. The authors review the papers on the subject, and think that in view of the absence of the subject in American text-books (definite recognition of the condition has been found only in Reed's work) that a report of the case is justified.

18.—See abstract in THE JOURNAL, xl, p. 1602.

19. **The Feeble-Minded.**—Barr considers that the defective or feeble-minded have been comparatively neglected while the state has been caring for the criminal and the insane. The

rapid increase of this class makes them a problem which must be attended to. Of the three classes, the untrainable idiot, the untrainable imbecile and the cunning and treacherous moral imbecile, the idiot is the most harmless and most easily disposed of. An asylum where he can be cared for under medical supervision is all that is required. Such an institution can be run very comfortably on a comparatively moderate income. The idiots can be taught, at least the better class of them, to be useful, to do household services and help in the care of others. The adult idiot or imbecile here can also have a peaceful home. A training school for backward children or the feeble-minded is a very different affair. High-grade imbeciles can be trained for certain employments, such as musicians, cabinet-makers, painters, seamstresses, carpenters, etc. Barr, however, points out the consequences of discharging such cases from the public care when they appear to have recovered. The immediate result is marriage and increase, for imbeciles they are still, though this may be imperceptible to the friends and the public, and it is transmissible. The moral imbecile is another difficult problem, and in the highest grades they are dangerous persons, capable of doing immense harm. For training imbeciles he believes in the colony system. They should never be turned out on the world, and on their own responsibilities.

21. **Ether-Vapor Ignition.**—Murray reports a case where ether vapor seemed to become ignited in the presence of a closed electric light, which he thinks was due to the electric spark. There was no other possible apparent cause. He has tried to experimentally reproduce the condition, but without success, in obtaining ignition. The fact that it has once occurred is of importance, and the surgeon or anesthetist should be on his guard.

23. **Puerperal Sepsis.**—Stone details the hospital methods that he thinks advisable in private practice. Some of these are difficult to put into practice, such, for instance, as shaving the vulvar hairs, etc. The principal thing, however, is the care of the hands, and he has used gloves in his private practice for two years with the greatest satisfaction. He thinks by their general use the morbidity of puerperal infection can be reduced at least one-half. He concludes with some remarks on the treatment of puerperal infection and insists on the importance of accuracy of diagnosis, recognition of the initial chill and careful examination of the pelvic organs at the initial period of the disease. As soon as the fever appears, excluding the breasts and constipation as causes, the patient should be transferred to a table and placed in the lithotomy position, with or without anesthesia, according to the circumstances, and after sterilization of the attendant's hands and external genitals, a systematic examination beginning with the perineum should be made. Until he adopted this method he was altogether unaware of the frequency in which infected wounds below the placental site were the cause of the trouble. It is a very common error to give an intrauterine douche before thorough examination, and in many cases transference of the infection to the placental site is caused by our initial efforts at treatment. The parts are examined upwards from the perineum to the fundus of the uterus with the greatest care, and wherever wounds are found they are aseptically treated with irrigations of sterile salt solution, which is sufficient in most cases to produce healing and disappearance of general symptoms. Retained discharges may be found to be the cause. If there are putrid remains of gestation products, these may be removed by the fingers supplemented by the use of some dull instrument. A common error is to mistake the roughened placental site for retained gestation products. Washing out the cavity with hot saline solution is usually sufficient; he protests against the use of antiseptic douches. The more radical procedures, such as hysterectomy, are indicated in very few instances. If cellulitis or peritonitis is present, an ice bag to the abdomen, followed later by prolonged and hot vaginal douches, aids in the absorption of exudate. If an abscess is present it is opened in the most accessible region.

24. **Tetanus Prophylaxis.**—Taylor advises the use of prophylactic injections of tetanus antitoxin in cases of toy pistol wounds. It has been the custom for the last two years at the Hudson Street Hospital in New York to inject 10 c.c. in each patient, and they are now practically rid of tetanus from this class of wounds.

25. **Surgery of the Prostate.**—MacGowan, in this concluding section of his article, notices the inconveniences of suprapubic operation and the possible dangers of urinary infiltration with hemorrhage, irregular cicatrices, deformity of the bladder neck, etc. Leakage of the suprapubic wound is annoying and may last for weeks. The difficulties of the perineal operation are not usually great. Its perils consist: 1. In the making of an irregular tear in the bulbous urethra by the assistant who holds the staff thrusting it awkwardly and violently through the bulb. This causes delayed healing of the urethral wound, and sometimes the formation of a fistula difficult to repair. 2. When the prostatic capsule is entered and an attempt made to enucleate its contents, no line of cleavage can sometimes be found, and persistence may lead to the tearing away of the organ from the pelvic tissues, causing urinary infiltration and infection. 3. If such fibroid growths are removed piecemeal with scissors and rongeur, it leaves a very irregular channel, which subsequently tends to contract, sometimes obstructing urination so that the patient is no better off. 4. There is also danger of tearing into the rectum, which once happened to MacGowan in a cancerous prostate, and which is liable to happen to anyone operating in a very dense or fibroid prostate. 5. When the bladder tissues have been greatly bruised by sharp stones before the operation and where the urine is hopelessly alkaline with all that that implies, all wounded surfaces within the bladder, and sometimes within the prostate, become covered with phosphatic incrustations. These are subsequently cast off or may have to be loosened by curetting somewhere between the third week and the third month. In one case he had to reopen the suprapubic wound on this account. In still another case, such sloughs came away through the perineal wound, which reopened apparently from this cause and subsequently closed itself. 6. Dangerous hemorrhage is not common by the perineal route unless the case is complicated by a tight stricture in the perineal urethra, requiring the severing of the bulb in the course of the operation, or unless the bulb is carelessly cut in making the opening in the urethra, but secondary hemorrhage is liable to occur. He has seen it now in two cases during the past year, following an attack of tenesmus which seemed to arise from an organized clot formed on one side of the bladder neck. When the packing was removed and the perineal wound practically closed, this clot was swept into the urethra and became fixed, causing tenesmus. The forcible contraction of the bladder neck on the clot loosened it from its vessel and a hemorrhage then took place into the bladder, filling it to distention in less than two hours. In one case he was able to stop the hemorrhage by breaking the clots up by a lithrotrite. In the second case he had to do a suprapubic cystotomy under most unfavorable conditions. 7. There is another danger where one or more small nodules are imbedded directly in the tissues around the internal urethral mouth or from nodules buried beneath the mucous membrane just inside the urethral neck. Their removal is necessary, but it may be followed by the tearing out of the whole posterior urethra. This is a disagreeable accident, but it does not necessarily interfere with later function. 8. In making the perineal incision in very large stout men with deep perineums, great care should be exercised to keep well away from the rectum with the skin cut. He has had trouble in having the anterior fold of the anus drawn into the wound, with leakage, though there was no cut in the rectum itself. The benefits of the operation are enumerated. The sexual power usually remains after operation, in spite of the teachings of the Necker school. In the great majority of his 49 prostatectomies and 29 Bottini operations, the results have been ultimately good. None have been positive failures. A few have dribbled for a time, but none permanentlly. He has never yet seen one of these cases where it was not necessary to urinate four or five times in the twenty-four hours, and does not look for it. He says, regarding prostatotomy by the

Bottini method, that it possesses a real surgical value and for certain prostatic obstructions it is to be advised.

26 *Scientific Work in Ohio State Hospitals. A. P. Ohlmacher.
27 Surgery of the Prostate, Pancreas, Diaphragm and Spleen. (Continued.) B. Merrill Ricketts.

26. **Scientific Work in State Hospitals.**—Ohlmacher notices the work that is being done in the various states at the central laboratories, to which the state hospitals contribute material, and gives the project of a plan he has made for a State Pathologic Institute for Ohio, which should, he thinks, be organized similarly to those of New York and Michigan. It should be open to properly qualified workers from the medical profession of the whole state. The plan includes the formation of a pathologic museum, and strictly scientific memoirs should be issued from time to time after the model of the *Archives of Neurology* of Great Britain. The laboratory should also send out popular bulletins for public distribution giving in plain language the results of scientific work whenever any distinctly valuable contributions in the direction of elucidating the nature of disease or indicating methods of prevention have been made. The government should be under the charge of a board of trustees representing the state medical association, the state hospitals and the state university, with the balance of power in the medical profession. Its immediate management would call for a director or chief with a corps of properly trained assistants of his own selection. He thinks the time is auspicious for such an institution and that the influence of the medical profession can be well exerted to this end.

St. Louis Medical Review.

34 Rubber in Windowing Plaster Casts in Compound Fractures. Hugh Crouse.
35 Artificial Feeding of Infants, or Care of Bottle-fed Babies. Hugh T. Nelson.
36 The Treatment of Enlarged Prostates. W. P. Carr.

29. **Mastoid Pain.**—Dunn reports cases where pain referred to the mastoid was due to gumma, relieved by specific medication, and to influenza. He also refers to rheumatism of the atlanto-axidian capsular ligaments as producing symptoms attributable to the mastoid. There is also a mastoid pain which is not due to mastoiditis, though associated with otitis, with which all aurists are familiar.

30. **Intestinal Laceration.**—Claybrook reports cases and reviews others in the literature where laceration of the bowel occurred from contusions without any external injury. He says that if we have a patient with a history of abdominal contusion, suffering pain, with marked tenderness and rigidity, thoracic respiration, absence of peristalsis, as shown by the phonendoscope and transmission of heart and respiratory sounds to the abdomen, with or without rapid pulse, shock or abdominal facies, vomiting or distention, etc., we ought to lose no time in confirming the diagnosis by exploratory laparotomy and deal with the conditions as found. Opening the bowel in these cases does not increase the danger, and we never know what is inside until we get at it.

37 *Dislocation of One-half of the Frontal Bone During Parturition. Stewart L. McCurdy.
38 *Adenoids and Their Treatment. J. F. Dickson.
39 The Changes in the Management of Laryngeal Diphtheria Treated by Intubation. Edwin Rosenthal.

37. **Dislocated Frontal Bone.**—McCurdy reports a case of dislocation of the frontal bone, which occurred during parturition, the bone being displaced outward. At the time when first seen, it was too late to replace it, and the brain has evidently adapted itself to the changed conditions. A spring band was applied with pressure pad, but little was accomplished.

38. **Adenoids.**—Dickson describes the condition and advocates operation, or at least medical treatment when symptoms indicative of these growths appear. If they are not large and are soft and friable, treatment directed to the nose and nasopharynx followed by local applications of tannic acid and glycerin or iodin and glycerin and internal medication such as syrup of iodid of iron or hydriodic acid and tonics may be all that is required. If they are large, hyperplastic operative measures are necessary. He prefers cutting operations to the cautery, and thinks it is better to use an anesthetic unless the patient is old enough to control himself. He discourages the use of a steel nail on the finger, considering it dangerous. For anesthesia, he prefers ether, next chloroform. Nitrous oxid, he says, is of too short duration for good work. The patient should be laid on his side, with his head hanging over the edge of the table. Good results of operation are noticeable within a week or ten days. After-treatment in the shape of sprays, etc., should be kept up for a few weeks after operation, as it helps to prevent recurrences.

44 *Cockroaches as Conveyers of Typhoid Infection. Rosa Engelmann.
45 *Blood Cultures in Lobar Pneumonia and Agglutination of the Pneumococcus. Edward C. Rosenow.

40. **Prolapse of the Rectum.**—The different methods of treatment for this condition are described by Halstead, who reports six cases. He concludes that all cases of mucous prolapse of the rectum will be best treated by resection of the protruding mucous membrane and suture of the cut end to the skin of the anus, as in Whitehead's operation for hemorrhoids. In mild cases clamping and cauterizing the linear folds of the prolapse may suffice to effect a cure. In recent reducible prolapse of all coats of the rectum, removal of the cause, if possible, with massage, gymnastics, and proper medication to improve the general health should be first tried. If they fail, amputation or intra-abdominal suspension is advised. In young children operative treatment of prolapse is seldom required. The removal of the cause, which usually can be accomplished, and rest in a horizontal position with tonics and massage will effect a cure in most cases. Among the commoner pathologic conditions having direct causal relation to prolapse in children are intestinal catarrh, rickets, phimosis and calculus. In old irreducible or in recent strangulated cases, the only treatment is amputation by Mikulicz's method. In old irreducible prolapse or in recent cases, where after a fair trial of palliative remedies they have failed, we have the choice of two methods, amputation or intra-abdominal fixation. At present no authoritative statement as to the value of colopexy can be given. It has the advantages of not being dangerous and of being easily performed. When it fails it does not leave the patient worse than before. Inguinal colostomy should never be performed except under special indications, as, for example, when prolapse is associated with obstinate colitis which does not yield to treatment or when stricture or malignant disease exists. Simple catarrhal inflammation or prolapsed rectum does not justify opening the colon. Rectopexy, if employed, should be used only in the lesser degrees of prolapse. In invagination of the rectum and colon it is of no value. In any case its disadvantages and dangers outweigh its advantages.

42. **The Negro.**—Howard remarks that the negro is structurally and psychically an animal, entirely apart from the white race, not capable of improvement. He is returning under present conditions to the atavistic state and is a social danger. The only good point he admits is that he is not vindictive.

43. **Nephritis.**—Croftan argues against an exclusive milk diet in nephritis, claiming that it does not meet the needs of the general nutrition. It contains too little iron, an excess of proteids and floods the system with fluids. Its effects on the renal epithelium are bad. It is apt to retard the healing process in subacute forms and is superfluous in chronic cases. Large quantities of water, of urea and of the phosphates, all of which are carried to the kidneys by this diet in excess, are irritants and harmful. Its effects on the other organs are also injurious mechanically, through the large amount of fluids and the effects on the circulation. The diet for nephritis should contain a minimum of proteids and of water in the acute cases, and the withdrawal of all food or its reduction to a small quantity is preferable to feeding with milk. In chronic cases a similar dietary is also required, though we are not at present able to formulate fixed rules. We do not know enough of the etiology of the condition to decide. He thinks the consensus of clinical experience speaks for more liberal feeding of kidney cases than is usually adopted, and decidedly against one-sided alimentation.

44. **Cockroaches and Typhoid.**—Engelmann gives the conditions in a typhoid epidemic in a certain limited district in Chicago, and describes the conditions, attributing the transmission of the disease to cockroaches.

45. **Pneumonia.**—The conclusions of Rosenow's article are as follows:

1. With improved technic, using for inoculation large quantities of blood, the pneumococcus can be recovered in all cases of pneumonia, and in obscure cases of pneumococcus infection blood cultures may be a diagnostic method of positive value. 2. Pneumococcemia in pneumonia does not mean a specially unfavorable prognosis. 3. On account of the difficulties involved, agglutination of the pneumococcus is, at present, of scientific rather than of practical value. 4. Normal and pneumonic blood and serum appear to have no bactericidal influence on the pneumococcus. 5. The interesting question whether lobar pneumonia is the primary result of a direct local infection of the lung or of a secondary localization in the lung of pneumococci in the blood is as yet hardly ripe for final discussion.

Bulletin of the Johns Hopkins Hospital, Baltimore.

June.

46 The History of St. Bartholomew's Hospital, London. Thomas McCrae.
47 *Cryoscopy as an Index of Renal Insufficiency in Surgical Diseases of the Kidney. Martin B. Tinker.
48 A Simple Electric Female Cystoscope. Thomas S. Cullen.

47. **Cryoscopy in Renal Insufficiency.**—Tinker has studied the effects of renal insufficiency on the freezing point of the blood and urine; that of the blood is normally about —0.56 C. below that of distilled water, with physiologic variation of about .02 degrees. The increase of the freezing point to over —0.58 C. indicates renal insufficiency. The urine, on the other hand, has a much wider range. Under normal conditions the freezing point of the urine varies between —0.9 and —2 C. A freezing point of above —0.9 is understood as an indication of renal insufficiency. A large number of cryoscopic examinations have been made, sufficient, it is thought, to prove the value of the test. Its advantage, Tinker says, over the usual quantitative chemical tests is that it gives an index of the total waste products excreted by the urine instead of that of a single constituent. He thinks that it might even alone be sufficient to determine the condition of the kidney, provided we can get the separate secretions of the two kidneys. The value of cryoscopic examination of mixed specimens alone is much inferior, however, to that of cryoscopic examination of the blood. In all doubtful cases both tests may be used in combination with the usual chemical tests with added certainty as to the state of the kidneys. The chief value of the test is in determining the prognosis in doubtful cases. If examination indicates a high degree of renal insufficiency, operation may be contraindicated. In other cases it may be of use in determining whether nephrectomy or a less extensive operation, such as nephrotomy or nephrolithotomy, should be given preference. The usefulness is a limited one in surgical cases, but when it is indicated it is very much needed, and the information it gives is correspondingly valuable. The method is simple and can be readily made by those little experienced in its use. It requires no special training and it does not take more time than many other methods.

American Gynecology, New York.

May.

49 Presidential Address—The Surgical Treatment of Early Diagnosed Cancer of the Uterus, More Especially by Hysterectomy. J. E. Janvrin.
50 *Ectopic Gestation. Etiology; Symptoms; Diagnosis; Treatment. J. H. Stealy.
51 Vesicofixation of the Uterus. N. J. Hawley.
52 *The Conservative Surgery of Lesions of the Appendages. Hector Treub.

50. **Ectopic Gestation.**—This condition, according to Stealy, is by no means infrequent; it is among the most serious conditions that we meet. It generally occurs in those near the middle of life with a previous history of sterility. The symptoms specially to be borne in mind are: 1. That the woman will have missed a period; 2, colicky pains; 3, bloody discharge from the vagina and irregular continuation of menstruation, often leading the woman to believe herself not pregnant. With few exceptions, and these dependent only on the woman's condition, the indications for operation are absolute. He says no case of "colic" in a woman capable of childbearing, especially one married, should be allowed to pass by without a suspicion of ectopic gestation. Any such symptoms in a pregnant woman should not be lightly regarded.

52. **Conservative Surgery of the Appendages.**—Treub finds in striking the balance for conservative operation that such procedures for salpingo-ovaritis offer a danger of death that ought to be estimated at 2 per cent. at the most; some chances of not giving complete relief, of being insufficient and necessitating a second operation either conservative or radical, and the certainty of not procuring for the patient a new malady, under the form of the anticipated menopause. Comparing this balance with that of radical operations, he concludes that medical treatment suffices in at least one-half of the cases of salpingo-ovaritis, but if it is insufficient or contraindicated, one should never at the outset perform a radical operation of any sort. The first operative stage should always be posterior colpotomy. When by means of posterior colpotomy it is discovered to be a matter of tuberculous affection, hysterectomy should be performed as soon as possible. In case of hydrosalpinx not yielding to repeated colpotomy and requiring other intervention, and where one wishes to try and remedy sterility in women, the conservative abdominal operations (resection, salpingotomy salpingo-ovaro-syndesis) are indicated. Salpingorrhaphy should be reserved as an accessory operation to a laparotomy performed for no matter what other indication.

June.

61 *The Plague Situation in San Francisco and the Problem of Chinatown. Woods Hutchinson.
62 *The Meaning of Uric Acid and the Urates. (Concluded.) Woods Hutchinson.
63 Hernia. E. N. Crockett.
64 The Sympathetic Nervous System in Health and Disease. D. M. Brower.

61. **The San Francisco Plague Situation.**—Hutchinson gives the history of plague in San Francisco with caustic criticisms of the late state authorities.

62. **Uric Acid.**—This second paper, also by Hutchinson, concludes the series. He ends it with the following propositions which seem to outline the most rational tenable view of gout and lithemia: There is no connection whatever between the production of urea and uric acid, hence interdiction and marked limitation of animal or of nitrogenous foods, as such, in gout is irrational. Uric acid in health comes from two sources, the larger part from the nuclein and purin bases of foods, the smaller part from destructive metabolism of the nucleins of the body tissues. It is the latter alone which is increased in gout and lithemia. These are only symptom names for a miscellaneous group of chronic toxemic processes of widely varied origin characterized by the production of uric acid and the urates. By gouty diathesis we mean the possession of a sufficient degree of resisting power on the part of the protective cells of the body to oppose the entrance of any poison, whatever its character or source, with consequent destructive metabolism and the production of uric acid, but not adequate to neutralize or successfully prevent its absorption. The uric acid of gout, like the phosphoric acid which accompanies it, is merely the result and measure of the destructive metabolism of the nucleins of the body cells, chiefly, it is probable, of the leucocytes in response to the invasion of poisons or toxins, organic or inorganic. Hence the use of lithia or other solvents is irrational and any apparent benefits are to be explained on other grounds. As most of the toxins setting up this destructive metabolism and consequent uric acid production are of intestinal origin or entry, the diet should be regulated wholly with regard to the diminution of intestinal fermentation and putrefaction. As animal foods are more appetizing and attractive, and are more apt to be indulged in to excess, their limitation may be found more frequently indicated than that of the vegetable foods, but sugars and starches are very often at fault. As uric acid and the alloxur group are not toxic, or only feebly so, and are not the cause of gout, the prohibition of foods even rich in nucleins and the purin bases, has no clinical basis, and is of doubtful utility, except as diminishing the attractiveness of the dietary. The rôle of the liver in gout is negative, from its incapacity to act as a poison filter, and to absorb or transform into harmless excretory substances the excess of toxins brought to it by the portal vein. The drugs found of value in gout owe their efficacy chiefly to their power of checking intestinal putrefaction or of preventing the absorption of its products or promoting their elimination.

Interstate Medical Journal, St. Louis.

June.

65 *Simplicity in Dealing with Abscess of the Appendix. Paul Y. Tupper.
66 *Etiology and Pathology of Puerperal Eclampsia. Max W. Myer.
67 Symptoms and Differential Diagnosis of Puerperal Eclampsia. C. A. Ritter.
68 Treatment of Puerperal Eclampsia. B. M. Hypes.

65. **Appendicitis.**—Tupper pleads for simpler methods of operation in appendicitis. He thinks it is best to leave the appendix alone in appendiceal abscess. We may weaken the abscess walls and cause rupture, and we can do no harm by its retention. He objects also to mopping or washing out the cavity. His own practice is simply to enter the abscess in the most direct way, making a free opening and then insert a gauze drain.

66. **Puerperal Eclampsia.**—Myer is inclined to favor Fehling's theory of the fetal etiology of puerperal eclampsia as well as an autointoxication from the maternal organism.

The Physician and Surgeon, Detroit and Ann Arbor, Mich.

March.

69 *The Ureteral Dilatations, Spindles, Reservoirs and Ampullæ Byron Robinson.
70 *A Few Facts Regarding Paretic Dementia. Irwin H. Neff.
71 *Medical Malpractice. William P. Lane.
72 *The Surgical Treatment of Smallpox. Laurel B. Sandall.

69. **Ureteral Dilatations.**—Robinson's article is a full detailed account of various swellings and contractions of the ureters and their relation to age and other conditions.

70. **Paretic Dementia.**—Neff holds that heredity has a large influence in the causation of paretic dementia, while the percentage of syphilitics is also too considerable to be disregarded. Other influences, however, may act in producing the same symptoms.

71. **Medical Malpractice.**—The relation of the physician to the law is discussed by Lane, who finds from the decisions of the courts that the physician or surgeon will not be held liable if he uses reasonable and ordinary skill and learning and exercises reasonable diligence and care. Mere errors of judgment are not grounds for conviction for malpractice. Gross carelessness or failure to exercise proper diligence and caution, regardless of his learning and skill, make him liable, and he will be more liable if he employs methods prohibited by law, and when he omits altogether the established mode of treatment and follows one that has proven injurious. He does not impliedly contract to cure, but if a contract be entered into the law of contracts will apply. When the defense to an action for malpractice is that plaintiff's own negligence contributed to the result, the burden of proving it is on the defendant.

72. **Smallpox.**—Sandall, from his experience in the Philippines, believes in the practice of opening the pustules freely. He would use antiseptic baths from the very beginning and keep the skin as nearly aseptic as possible. As soon as the spots become vesicular, open the top and remove all contents, applying antiseptic solution to the whole open surface. The pustules, after they have formed, should be treated in the same way and the skin kept free from pus. The vesicles once thoroughly opened and destroyed do not proceed to pus formation and absorption of the poison is avoided.

73. **Provisional Hemostasis.**—Fowler gives the history of provisional hemostasis in surgery, and reports cases in which he has used Crile's method of compression of the common carotids with advantage. He considers the possibility of accidents in these cases avoidable by proper care as a rule, and that there need be little said as regards the possibility of permanent injury to the vessel. In his experience there were no bad effects excepting in one case in which aphasia was produced, but this was undoubtedly due to some lesion in the handling of the brain. The case was one of intracranial neurectomy after Abbe's method. The brain was elevated during the operation and a sensory aphasia developed afterward. The only explanation to be given was that it was due to some lesion of Broca's convolution owing to the general atheromatous condition of the arteries of the brain.

7 *The Physiologic Action of Ethyl Bromid and of Somnoform. Sydney W. Cole.

1. Muscular Mechanism.—This second Croonian lecture by Beevor is a continuation of the one in the last issue devoted to the mechanism and the action of the muscles of the upper extremities and the trunk. Like the former it is incapable of being abstracted.

7. Somnoform.—This mixture, which has been used as an anesthetic, largely in France in minor operations, is made up of ethyl chlorid 65 per cent., methyl chlorid 30 per cent., and ethyl bromid 5 per cent. It has been investigated by Cole, who

offers his conclusions as a preliminary communication, as follows:

The chief indications that my experiments afford as to the use of somnoform as an anesthetic are: 1. The chief danger being a paralysis of respiration, a careful watch must be kept over the respiratory movements. 2. Owing to the depression or paralysis of the peripheral endings of the cardio-inhibitory fibers and the comparative slight action on the heart itself there is no danger of heart failure, provided respiration has not ceased. 3. After cessation of the respiratory movements it is easy to restore the animal by artificial respiration. I am of the opinion that the paralysis of the cardio-inhibitory fibers by ethyl bromid renders that drug a very valuable anesthetic. Embley has recently shown that the sudden death that not infrequently occurs in chloroform anesthesia is due to inhibition of the heart through stimulation of the cardio-inhibitory center. This is usually only seen in the early stages of chloroform administration, the danger passing off when the medullary centers are exhausted. I venture to suggest that a valuable anesthetic for prolonged operations could possibly be obtained by combining ethyl bromid with chloroform. During anesthesia produced by ethyl bromid the vagi are paralyzed; chloroform would then be deprived of one of its great dangers. It might be possible to get well past the stage of excitation into that of depression of the medulla before ceasing to give ethyl bromid, and maintaining anesthesia by chloroform alone, ethyl bromid being discontinued owing to its paralytic effect on respiration. I hope shortly to give an account of experiments I am performing to test this possibility.

14 *A Simple Expedient in the Estimation of Sugar by the Copper-reduction Method. S. Archibald Vasey.
15 Preliminary Note on the Use of Chloroform in the Preparation of Vaccine. Alan B. Green.

9. **Intubation.**—Fairbank's article is based on an experience of 33 cases. He remarks on the scarcity of literature on the subject in Great Britain since the introduction of antitoxin. Taking his own cases with those of Kellock and Basan, he has 78 cases of intubation associated with antitoxin treatment, with 76.9 per cent. of recoveries. Roux mentions 128 cases, with a percentage of recoveries of 62.8. According to his own experience the greater the skill of the operator the better the results. The operation is an easy one, provided the operator has had practice, and in experienced hands is practically free from danger, though death may occur from syncope, as in a case reported. He thinks the sizes recommended by O'Dwyer for the different ages are rather small, and that the size of the child should be considered rather than its actual age. The male larynx is a little larger than that of the female of the same age. Fairbank believes in retention of the string as long as the tube remains, and in all his cases the thread was left attached to the tube. He fixes it to the cheek with a piece of strapping, and thinks the children soon get used to it. In only one of his cases was there any trouble from the child biting through the string. Abrasions and ulcerations of the epiglottis can be avoided by careful attachment of the string on the cheek, and any little disadvantage on this score is compensated for by its advantages otherwise. After the tube is in place the child should be laid on his side to facilitate the escape of mucus from the side of the mouth. The coughing soon gives way to peace and quiet, and the child is at last able to sleep. Feeding by the mouth is possible in a large number of cases and is worth trying. It is an important point to decide when to take out the tube. In the early stages it should be removed every twenty-four hours for cleaning and to allow expulsion of mucus. He suggests the following rule in the average case. The tube should be removed and replaced at the end of twenty-four hours; removed at the end of another twelve hours and the result awaited. If the tube has to be replaced it should again be removed after twenty-four hours. After it is again replaced it can be left in for forty-eight hours, and will then usually enable the child to dispense with it. Attempts at discontinuing the use of the tube before thirty-six hours are almost invariably unsuccessful. The longest recorded case is one reported by Brothers, in which the tube was held for fifty-eight days with interruptions to the end of the twenty-first day. In one of Fairbank's cases the tube was only required thirty-two hours; the longest case required it until the thirty-fifth day. Its extraction by means of the string is, of course, easy, but an extractor is a dangerous weapon and requires the greatest skill and gentleness in its use. Vomiting after or during intubation is rare and occurred in but one of his cases. Coughing up of the tube is also rare if a suitable size is chosen. If immediate relief is not afforded by intubation, or if the child's distress increases, the tube should be removed, and may bring out with it the membrane or have it coughed out soon after. Tracheotomy should not be performed until the result of removal of the tube has been seen. The membrane may block the tube at any time during the first few days. It is advisable to explain to the nurse the conditions that indicate the need of immediate extraction. Profuse watery expectoration is sometimes observed with great restlessness. By laying the child well over on its side and frequently clearing the throat with a swab, relief will often be afforded. Severe ulceration of the laryngeal membrane is uncommon. In his series 3 secondary tracheotomies were performed, but he is now convinced that they were unnecessary. He analyzes the 5 fatal cases, 1 of which died during the operation of intubation. In another case the child died a day after intubation. There were signs of tuberculosis and general tuberculosis was found. In the third case pneumonia developed and caused death after removal of the tube. In the last case the patient died three days after admission from anuria and bronchopneumonia. He thinks in most of these cases at least the fatal result could not have been avoided if primary tracheotomy had been performed. He notices one or two instances of ugly ulceration from the use of the tube in non-diphtheritic cases. Abrasions or ulcerations may occur very rapidly in debilitated subjects.

11. **High Altitudes.**—Zangger's warning in regard to the dangers for elderly people of rapid railway journeys up to a considerable elevation has already been noticed in these columns, page 1547 of the last volume. A difference of altitude of a little over 8,000 feet, during the mild weather and free from wind, may cause a decrease of blood pressure and of the vital capacity with obvious cyanosis and an increase of the pulse rate. He says people with heart disease hardly need to be warned against making mountain ascensions. In case of elderly people with vascular apparatus impaired to a degree, yet apparently in good health, he would warn them to try an ascension of 3,000 or 4,000 feet before attempting greater elevations. In any case they must acclimatize themselves or become accustomed to the reduction of pressure by stoppage at intermediate stations. He advises them not to try to go above 9,000 feet unless under careful medical supervision. The decrease of atmospheric pressure is of importance and the chemical features of respiration also undergo a change. The amount of oxygen which is absorbed sinks while the respiratory quotient rises. This means that the bodily tissues, inclusive of the heart, receive less than the usual amount of oxygen, and it is also to be mentioned that the muscular substance of the heart is especially liable to suffer from the deficient blood supply. A very important factor which is usually overlooked is the reduction of temperature of the atmosphere, which may be as much from 30 to 60 degrees F., causing the peripheral blood vessels to contract and remain contracted. This must affect the blood vessels and the distribution of blood in the whole system, and on return to low ground considerable oscillations of the blood pressure and a rise of some duration may take place which may explain the occurrence of apoplexy. It must be remembered that the vessels of the brain have not yet been proved to possess vasomotor nerves so that the regulation of the cerebral pressure may be very inconsiderable. He remarks also on the acute dilatation of the heart liable to be produced, and this may occur in spite of its apparent improbability in persons who have been carefully conveyed up to high altitudes without any muscular effort whatever, and may not be perceptible until twenty-four or thirty-six hours after the excursion has been made. It is advisable to immediately send the patient to a lower ground, and better by carriage than rail-

way. Absolute rest in bed for several days is sometimes necessary. When insomnia occurs, wet packs to the lower extremities or abdomen, bromids and even morphin may be given. The heart can be stimulated with caffein or camphor, but not with digitalis. The bowels should be in good functional order and free diaphoresis encouraged. Externally counter-irritants may be applied to the region of the heart and in severe cases venesection may be performed. The heart must be kept comparatively quiet for several weeks or even for months, after the severer symptoms with dilatation, etc., such as dyspnea, congestion, precordial pain or possibly angina pectoris. He reports a case in detail where a patient 68 years of age, apparently in good health, had marked dilatation from a railroad trip carrying him to an elevation of 8,505 feet. He was quite well during the trip and for the next thirty-six hours, but at its termination he was still at an elevation of 5,315 feet. The symptoms showed themselves while taking a walk.

12. **Sleeping Sickness.**—Twenty out of 34 cases revealed the presence of the trypanosome in the cerebrospinal fluid in sleeping sickness. Castellani gives its apparent relations to the disease, which are practically the same as those already noticed in THE JOURNAL of July 4, p. 64. In a note by Sir Michael Foster it is stated that Col. Bruce, R.A.M.C., who has been continuing the investigation begun by Dr. Castellani, finds the tryaposoma in every case in the fluid obtained by lumbar puncture (38 cases), and has found it in the blood of 12 out of 13 cases.

14. **The Sugar Test.**—The drawback to the original method of Fehling is the formation and suspension of red cuprous oxid in a blue solution. It occurred to Vasey that instead of adding a reagent to form a soluble compound to the cuprous oxid as it is produced in Pavy's and Gerrard's processes, an inert powder, preferably of a clear white color, may be employed, so as to entangle the precipitated oxid and carry it rapidly to the bottom of the solution, leaving above a clear liquid in which the faintest trace of blue can be seen. He found that precipitated chalk or barium sulphate fulfilled the requirements admirably. To the measured quantity of Fehling's solution (generally 10 c.c.), suitably diluted, he adds about two teaspoonfuls of a finely precipitated calcium carbonate or barium sulphate. The mixture is then raised to the boiling point, being gently stirred with a glass rod during the whole time. The solution in which the sugar has been dissolved is then run in after the usual manner. It will be found that the red cuprous oxid will be deposited on and evenly distributed through the chalk slime or barium sulphate, which rapidly subsides so that the true color of the clarified supernatant liquid is quite easily seen. In this way the exact point of transition from a trace of blue color to a colorless solution can be sharply noted. The process is rapid and extremely accurate according to a number of estimations made by him with standard solutions of sugar, diabetic urines, etc., and he thinks it will be found convenient in clinical practice.

19. **Bactericidal Power of Fresh Milk.**—Nineteen series of experiments are described which illustrate that "living" milk, that is, freshly milked or at least within five or six hours, has bactericidal power for the bacteria usually encountered in milk and also for the diphtheria bacillus. The growth of the bacteria is not affected by immediate transferrence of the milk to a low temperature. The number of germs constantly diminished in the milk as it stood for the first few hours, after which they constantly increased.

21. **To Retain Color of Anatomic Specimens.**—Claudius points out that in the ordinary methods of preserving specimens the hemoglobin is soon dissolved or discolored, and with it is lost the natural appearance of the tissues. He has succeeded in preserving the color of the hemoglobin by transforming it into a carbonic oxid combination which is much more resistant and stable. This is done by saturating the specimen with illuminating gas, which always contains a certain percentage of carbonic oxid. The specimen is placed in a saturated solution of ammonium sulphate, filling about one-third of the tight vessel, and then the gas is introduced. Specimens thus prepared are as bright to-day as when dissected out fourteen weeks ago.

22. **Joint Involvement in Sarcoma of the Long Bones.**—This communication from the hospital in charge of Oscar Bloch mentions that in 30 cases of osteosarcoma of the long bones, in 15 the affection at first presented the clinical picture of an inflammatory arthritis, and in 6 of the latter the knee was involved and supposed to be the sole lesion at first. In differentiating, the patient's constitution, age, sex, family antecedents or preceding trauma afford no characteristic data, but tuberculosis, malignant tumors, syphilis and tabes must be excluded. Fever may or may not be present in case of osteosarcoma. The pain is occasionally characteristic, but its radiation to a sound knee may be deceptive. The pain in case of a sarcoma usually starts always at the same point and spreads thence like a neuralgic pain along certain nerve tracts, and occurs spontaneously, both at rest and during exercise, sometimes most severe at night. When such pains are accompanied by an apparent joint affection, resembling a white swelling or hydrarthrosis, the possibility that the affection may be of a sarcomatous nature should suggest itself. Usually, however, the pains are those of any inflammatory joint affection. The irregular shape of the tumor and its irregular consistency are important signs of sarcomatous involvement, also the infiltration of the lig. cruciata, causing the filling out of the popliteal space. This does not occur to the same extent in case of synovitis or tuberculosis. The movability of the joint is frequently retained and is important for the differentiation. The sarcomatous lesion is not benefited by immobilization, elevation and repose like an ordinary arthritis, and suffers when a compressing bandage is applied, edema usually forming around the edges of the bandage. These differentiating signs may be all absent, but they are encountered in a certain proportion of cases.

23. **Duodenal Stenosis Below the Papilla.**—When the stenosis is above the papilla the clinical picture resembles that of pyloric stenosis, but when it is farther along in the intestine the characteristic symptoms are admixture of bile with the stomach contents, alternating positive and negative findings of free hydrochloric acid, and more or less pronounced acholia of the feces. These symptoms were all combined in the case described by Madsen. The patient was a field hand, 41 years

old, the disturbances dating from a little more than a year before. They commenced with severe pains in the cardia evening and night, obstinate obstipation and progressive weakness and emaciation. One day, after severe vomiting, an attack of tetany developed. He was treated by gastroenterostomy, and after a period of improvement died in cachexia.

24. **Danger from Introduction of Bag Dilator.**—Muus warns that it is wise to determine whether the head is movable before attempting to introduce the dilatable bag. In a recent experience the head was immovable and the forceps slipped, perforating the uterus wall.

26. **Transmission of Human Tuberculosis to Cattle.**—Fibiger reviews the various reports that have appeared in the last year or two on the communicability of human tuberculosis to cattle. He finds that various authors have reported 61 attempts at inoculation of cattle with human tuberculosis, with positive results in 41, that is, tuberculosis was induced in 51 out of 81 animals in these 41 experiments. In 74 experiments on 108 cattle, swine and goats the results were positive in 52, that is, on 73 of the animals. Consequently, two-thirds of all the experiments were successful and two-thirds of all the animals were infected. Koch's assertions on this subject are therefore untenable. The tuberculosis is generally restricted to the part or organ inoculated, but occasionally the infection spreads and the disease becomes universal. As a rule, human tuberculosis is not so virulent for cattle, but there are numerous exceptions in which the disease develops as rapidly and with as much intensity as from virulent bovine tuberculosis. Fibiger states that besides the animals mentioned above, dogs, cats, sheep, horses, asses and monkeys have been inoculated with human tuberculosis and always with a certain proportion of positive results. The material with which the animals were inoculated included tuberculous sputa, scraps of tuberculous organs, cultures of tubercle bacilli and tissue from lesions in tuberculous meningitis, arthritis, synovitis and lymphadenitis, as well as pulmonary and renal tuberculosis. On an average 45 to 57 per cent. of the inoculations under all these varied circumstances resulted positively. Fibiger refers to his own extensive experiments, reported last year in the *Hospitalstidende* No. 37 and the *Berliner Klin. Wochft.* No. 38, which confirm the results obtained by others, and are included in the above figures. He remarks in conclusion that he can not accept without some reservations Behring's statement that cattle can be rendered immune to human tuberculosis by inoculation with bovine tubercle bacilli and *vice versa*. He also believes that the bacilli of bovine tuberculosis are more dangerous for man than human tubercle bacilli.

27. **Etiology of Hyperacidity.**—Borgbjerg did not find neurasthenia, hysteria nor hypochondria in any one of the 93 cases of hyperacidity which form the basis for this article. On the other hand, constipation was almost constant. In 99 cases of severe constipation in women he found hyperacidity in 33, that is, in 33.3 per cent., while in 68 cases of constipation in men there was hyperacidity in 60, that is, in 88.2 per cent. In 25 per cent. of the male cases there was abuse of tobacco or alcohol, of tobacco alone in 10 and of both combined in 2. In 20 cases of hyperacidity without constipation there was abuse of tobacco or alcohol in 50 per cent., and all were improved by suspension or reduction of the tobacco or alcohol. In one case the hyperacidity could be explained by hasty eating and insufficient mastication (during a trip to America, he qualifies, in parenthesis). In another there was dilatation of the stomach, which subsided under careful dieting. He found "nervous" symptoms in only 6 cases, and not pronounced in any. He concludes with the description of a case in which the hyperacidity and headache were evidently of reflex origin from a small reducible inguinal hernia; both vanished as soon as a truss was worn.

30. **Clinical Picture of Cerebrospinal Meningitis.**—In 1898 an epidemic of 161 cases of cerebrospinal meningitis was observed at Copenhagen between April and July. Sorensen reviews the clinical picture in 60 of these cases, comparing it with the autopsy findings in 19. Lumbar puncture was done in 51, but no fluid could be obtained in 17. In 31 of the others examined under the microscope the meningococcus was found in 27. In the cases in which the onset was severe and the disease fatal in a month or less, meningitis was always found, while in the cases with a slower course there was only hydrocephalus. No less than 4 of the 19 cases that came to autopsy showed tuberculous lesions. Hence the finding of tubercle bacilli in the cerebrospinal fluid does not necessarily exclude epidemic meningitis. He describes the particulars of a large number of cases, with 23 temperature curves.

32. **Deprivation of Salt in Treatment of Epilepsy.**—Madsen thinks that the results observed to date indicate that the bromids actually take the place of sodium chlorid in the organism when the latter is deprived of its ordinary supply of salt. He has followed Balint's directions for bread with sodium bromid instead of salt, in a number of cases of epilepsy, and tabulates 7 in detail. Out of the total number only one had any more seizures during the five to seven months following, although previously they had had from 1 to 28 a month. The one patient in whom the seizures recurred had only 2 in the course of five months afterward, to 34 in the preceding nine months.

34. **Lupus Cured with Ethyl Chlorid Refrigeration.**—Nordentoft extols the convenience and inexpensiveness of this method of treating facial lupus with which he had been eminently successful in a case. Dethlefsen first announced the efficacy of this treatment and reported a case in 1900 and one more in 1901, but has not published the remote results. The patient in the case here illustrated was a woman of 64, who had suffered for years from lupus of the nose. The cuts show that she had entirely recovered after 48 seances, at first daily and then once a week.

38. **Banti's Disease and Splenomegalia.**—In the case of Banti's disease reported, the endothelium of the venous capillaries of the spleen was much swollen and contained numerous red corpuscles and fragments giving the iron reaction. This has never been observed before, Borissowa states. The bone marrow was apparently normal only that the elements were more crowded than usual, actually suggesting exaggerated activity on the part of the marrow.

55. **Lysol Intoxication.**—After observing a fatal case of lysol intoxication, Hammer experimented with it on laboratory animals and looked up the subject in the literature. He is convinced that in his case some of the 1-per cent. solution of lysol injected into the uterus on account of a febrile condition following delivery with placenta previa, was aspirated into a vein. The lysol was thus carried to the brain and caused symptoms of collapse. These subsided, but a part of the solution must have remained in the vein and caused erosion of the endothelium with local thrombosis later. This thrombosis gradually extended centralward with fatal results. The solution of lysol for intrauterine irrigation in obstetric cases should always be weak and never be used under strong pressure. Especially in case of placenta previa great caution is necessary on account of the aspirating tendency of the gaping veins.

56. **Vegetarian Diet in Gynecology.**—Theilhaber attributes many of the ills that female flesh is heir to, especially in the well-to-do classes, to over-eating. He recommends a varied vegetarian diet, that is, excluding all parts of the dead animal, but allowing milk, eggs, etc., as products of the living animal. His experience includes 300 cases, but only 200 carried out his instructions for six months, at least, as directed. He has found this diet very valuable in various nervous affections, in the troubles of the menopause, in nervous insomnia, pruritus vulvæ and general pruritus, hemorrhoids, etc., and in one case of protracted galactorrhea, and thinks it would be advantageous in pregnancy nephritis or neuroses, but has had little opportunity to test the latter. In case of constipation or flatulence, the gas-producing substances must be excluded, but a careful selection will render the vegetarian diet very useful under these circumstances. Obese patients lost flesh, but others did not, as a rule, and none exhibited any loss of strength. He refers to the endurance of the Japanese, who eat little meat, as also the Trappist monks. He thinks that time will yet show that many obstinate nervous affections may be cured by abstention from meat.

58. **Protracted Lactation.**—In Nussbaum's two patients the galactorrhea continued for a year or two after the child had been weaned, reducing the patient to emaciation. The morbid tendency was cured by a compressing bandage, mild laxatives and small repeated doses of antipyrin. Zeitlin has published in a Russian journal a case in which the mammary glands continued their secretion for five years, although the patient had suffered from a metritis dissecans and amenorrhea in the interim.

59. **Aseptic Dilator for the Cervix.**—Müller uses a laminaria tent enclosed in a rubber cover. The latter is sterilized by boiling. The tent is held in place with a Hodge ring pessary, and a rubber bulb and tube supplies the moisture to the laminaria inside its rubber cover.

61. **Differentiation of Streptococci with Blood Agar.**—The use of blood agar has rendered possible the separation of streptococci into two groups, of which the one found in erysipelas is more malignant. The fact that the growth of the other is checked to such an extent by the blood agar justifies the hope that affections due to this germ, which Schottmuller calls Strept. mitior viridans, may prove to be amenable to serum treatment. He has also succeeded with the blood agar in differentiating a hitherto undescribed variety, the Streptococcus mucosus, which he isolated in 7 cases, all but 2 fatal.

62. **Necrosis of Gall Bladder.**—Czerny reports 2 cases, one terminating fatally. Both belong in the class of masked gallstone affections without characteristic colics. He operated on both, one requiring a second intervention. He found at the autopsy of the one and at the second operation in the other case that he had overlooked a gallstone. He usually operates conservatively on the gall bladder, restricting his intervention to mere cholecystostomy with water-tight drainage and suspension of the gall bladder. The fistula heals in about three weeks, and 85.7 per cent. of all his gallstone patients have been permanently freed from their disturbances by this easy and comparatively harmless intervention. He describes his technic in detail.

64. **Adhesion of Pericardium Treated with the Talma Operation.**—As a last resort, the Talma operation was performed, but without results, except a temporary improvement.

71. **Operative Treatment of Detachment of Retina.**—Müller's experience has shown that the cause of this condition is either an inflammatory exudate in case of choroiditis or a hemorrhage or a transudation due to venous congestion in the choroid, the precursor of acute, circumscribed atrophy of the choroid, and implicated in the tension. There is also a possibility of laceration of a coat of some vessel. The transudation may be due to compression of the vessels in the choroid by a tumor, or it may be the result of some affection of the blood, as in case of Bright's disease. The operation he suggests and has successfully performed on 7 patients, aims to put an end to the tension of the choroid noted in high myopia, and also to the distention and stretching of the normally located retina. It consists in excision of a strip of the sclerotic coat, 8-10 mm. wide by 20 in length, from the outer portion of the posterior segment, leaving the choroid intact and only allowing so much of the subretinal fluid to escape as is required by the reduction in size of the capsule of the eyeball. The rest is readily absorbed. The details of the operation are described at length, with the clinical cases in which it has been performed to date. The results, he thinks, justify him in announcing this method of treating detachment of the retina as causal and effective. Neither the duration of the detachment nor the degree are any obstacles to the complete and permanent reposition of the retina by this method. The restoration of vision depends on the progress of the accompanying anatomic lesions. Detachment of many years' standing offers little prospect of restoration of much vision, and when the detachment occurs at the macula, restoration of function can scarcely be anticipated for the latter. The operation includes temporary resection of the wall of the orbit.

73. **Effective Serum Treatment of Hay Fever.**—Dunbar's announcement that he had succeeded in isolating the substance

which caused hay fever and in producing an antitoxin for it, was duly chronicled in THE JOURNAL of April 4, page 943, ¶47. This communication gives further details, stating that time has only confirmed the correctness of his assumptions as established by a very large number of tests on hay fever subjects who have thronged to him in the hope of relief. Dunbar suffers himself from hay fever, and has been studying it for years. The toxin which causes it in the predisposed, and in them alone, is a soluble starch grain in the heart of the pollen of grains and grasses. He was able to induce a typical attack of hay fever with asthma by subcutaneous injection of this toxin in winter. The serum of animals inoculated with it protects susceptible subjects against infection with the pollen toxin, and there is every reason to suppose that it will protect against actual hay fever. The serum is perfectly harmless, but he does not give it to any one but physicians, and they must apply directly to him at the Institute of Hygiene, Hamburg, Germany. He notes the fact that hay fever occurs almost exclusively among the educated classes, affecting men and women who are under some mental and physical strain and compelled to be out of doors more or less. Among merchants and manufacturers, it usually affects those who are obliged to take long business trips. Physicians are peculiarly its victims; in his statistics fully 10 per cent. were medical men. The women victims are those who travel much or practice vocal or instrumental music or keep up a large household or have passed through numerous pregnancies. His statistics also seem to show that the prevalence of influenza has something to do with the increasing number of hay fever victims. The summer of 1902 was so cold and rainy that the grasses did not ripen until two weeks later than usual, and all the hay fever subjects mentioned the fact that the onset of their annual scourge was delayed two weeks beyond the usual date. Thost advises persons subject to hay fever to treat any concomitant gout or catarrh before hand, so as to enter the hay fever season in their best physical condition. Alcohol and tobacco should be avoided as the date approaches, with all other irritants and the body should be hardened by cold and cool sponges, air baths, etc. A certain protection is afforded by keeping indoors, in cool rooms with the windows tightly closed and the car windows closed when traveling. The eyes may be treated by local measures, cool applications, instillation of cocain, holocain or adrenalin. One ophthalmologist found that he derived relief from instillation of a .2 per cent. solution of silver nitrate, and in a slightly stronger solution this may be applied to the nose with benefit. Rinsing the nose with tepid saline solution, greasing it or plugging the nostrils with cotton, possibly mentholized or formanized cotton are also useful preventive measures. Glaring sunlight should be warded off with blue glasses compressing the nose. Sprays, etc., are more effectual when they are applied to the upper part of the nose at the terminals of the olfactory nerve. Holding the handkerchief to the nose or wearing a gauze veil is a protection when traveling, and small nose filters have also proved useful. Quinin is a good tonic in these cases and the usual measures against asthma will afford relief. In sending hay fever patients away from home, the blossoming time of the gramineæ must be borne in mind and avoided if possible.

81. **Prevention and Treatment of Hydronephrosis.**—This communication from Senator's clinic calls attention anew to the fact that a diseased kidney eliminates not only less water, but also less salt. This was confirmed by a long series of experiments with salted food on nephritic subjects. The diseased organ eliminated less chlorids, both quantitatively and proportionately than the other kidney. This was especially marked in case of hydronephrosis. The proportion of salt in the urine from the diseased kidney did not vary from the usual amount, but, on the other hand, the proportion of phosphoric and sulphuric acid in the urine was about the same for each kidney, in notable contrast to the proportion of salt. These and similar facts observed have convinced Strauss that dropsy is not only accompanied by a retention of salt, but has also some direct causal relation to it, and that the salt retention is due to the kidney itself. The practical application of these conclusions is that in all cases of nephritis, or at least those with a tendency to edema, the intake of salt should be restricted and its elimination promoted. The dietary should be as free from salt as possible; milk is particularly valuable on this account. If saline infusion is necessary a hypo- rather than an isotonic saline solution should be used, or, better still, substituted by Schücking's sodium saccharate or fructosate solution. (Formula was given in THE JOURNAL, XXXIX, p. 454, ¶83.) The proportion of salt in the edema remains unaltered, and consequently retention of 6 gm. of salt means the retention of a quart of water to hold it in solution. Treatment should aim to promote the elimination of salt by diuretics known to increase it. Among these are the heart tonics which by inducing better conditions in the circulation augment the elimination of salt. Nature strives to accomplish this spontaneously, and the transformation of a chronic parenchymatous nephritis into a secondary contracted kidney depends in large measure on the ability of the heart to become hypertrophied. Caffein takes the lead among the diuretics proper. In the experiences reported the amount of water eliminated was frequently normal, notwithstanding the retention of salt. The edema vanished when by medicinal or other measures polychloruria had been induced in addition to the polyhydruria. The hydruria was often capriciously variable on different days, but the proportion of salt was a constant figure. He concludes by urging the necessity of determining the proportion of salt in the urine as a routine measure, remarking that retention of salt without edema is the incipient stage of hydronephrosis or general dropsy later. He recommends for the purpose Achard and Thomas' bedside approximative test as simple, easy and sufficiently accurate. [This test was described in the *Bull. Soc. Hop. de Paris*, 1902, No. 22. It is a reversal of the ordinary silver solution test. Instead of adding the silver solution to the urine, the latter is added to a given amount of the titrated silver solution (29.075 per 1000, of which 1 c.c. precipitates 1 eg. of chlorids). A graduated Esbach tube is used, in which 5 c.c. of the silver solution are poured and three or four drops of a 1 per 5 solution of potassium chromate or bichromate added. A silver chromate is formed, but as soon as the urine is poured into the tube and shaken up a silver chlorid forms and the chromate is decomposed, the reddish brown tint of the fluid changing to a clear yellow. The tube is graduated with a scale calculated as follows: 3.3 c.c. represents 15 gm. of chlorid per 1000; 5 c.c. represents 10 gm.; 7.1 c.c. represents 7 gm.; 10 c.c. represents 5 gm.; 12.5 c.c. represents 4 gm.; 14 c.c. represents 3.5 gm.; 16.6 c.c. represents 3 gm., and 20 c.c. represents 2.5 gm. The silver solution may be diluted or the urine, rectifying the scale readings to correspond. The urine must be acid, and a little vinegar may be added if necessary. The urine should be poured in up to each mark in turn, stopping and shaking at each one to note if the reaction occurs. It is wise to test with urine taken from the total amount for twenty-four hours, bringing the amount up to one or a round number of liters by adding water, multiplying the readings to correspond as the scale is computed for one liter.—ED.] Strauss concludes with the statement that treat-

ment of patients on these lines has afforded results which unmistakably demonstrate that we are on the right road in basing prophylactic and curative measures in hydronephrosis on the retention of the chlorids. It is possible, he adds, that further study of the chemistry of the urine may build up a firmer foundation for the new physical-chemical tests of kidney functioning. [Widal and Lemierre reported at the meeting of the Paris "Soc. Méd. des Hop.," June 12, that they had been able to induce the formation of edema at will in 2 cases of nephritis, predominantly epithelial, by addition, for six to ten days, of 10 gm. of sodium chlorid to the day's rations. The weight increased as the edema formed, and subsided when the patients were put on a milk diet without salt and the edema vanished. In 4 cases of arteriosclerosis with interstitial nephritis the ingestion of sodium chlorid had no influence on the edema. Analysis of the cases shows that salt induces edema when there is already marked retention of the chlorid, but not when it is being eliminated normally or above. Dufour mentioned that in 2 tabetics under specific treatment with addition of salt the knee-jerk returned in one and this and the Achilles-jerk in another. About 2 or 3 gm. of salt were taken daily for months. The knee-jerk on one side vanished afterward in one case subsequent to a gastric crisis. Other facts in regard to alimentary chloruria in nephritis have been published by various French authors recently, some pointing out the large proportions of salt eliminated in chronic sclerous nephritis, others the gravity of the prognosis in nephritis accompanied by retention of chlorid. Others still suggest that the chloruria may not be exclusively dependent on the kidneys, and that the kidney lesions are not directly responsible for the hypochloruria.—ED.]

82. **Saliva as a Factor in the Cure of Disease.**—Bergmann styles the gargle "therapeutic trifling," inefficient for any real purpose. He thinks, on the other hand, that the saliva reaches every part of the throat and can be made the vehicle for therapeutic applications. To promote the flow of saliva he orders "chewing tablets," and advocates their use in throat affections, in dyspepsia, obesity and edema. He has a special medicated or non-medicated tablet for each. The alkaline saliva is particularly beneficial in acid dyspepsia. In case of obesity or edema the accumulating saliva is expelled and the large amount of fluid that is thus eliminated has a surprisingly favorable action in reducing the obesity or edema.

87. **Yohimbin as a Local Anesthetic.**—Haike proclaims that, combined with suprarenal extract, yohimbin is proving an ideal anesthetic for ear and nose work. The combination has all the advantages of cocain with none of its drawbacks.

110 Lighting Strokes and Hemorrhage from Eyes. A. Topolanski.—Blitzschläge und Augenblutungen.

90. **Mistakes in Diagnosing Stomach Affections.**—In one of the 4 cases described the clinical picture of pyloric stenosis was presented, but the obstruction was found to be at the cardia instead. The tumor could not be palpated, as it was fastened down under the liver. The stomach tube could be introduced for 70 cm., and the same amount of fluid poured in could be siphoned out again. The vomiting recurred in the afternoon, and there were no disturbances in swallowing, but esophagoscopy would have disclosed the lesion if anything had called attention to this location of the tumor. In another case the apparent stenosis of the pylorus was caused by the fixation of this part of the stomach in the gall-bladder region owing to unsuspected gallstone inflammation. Another case was diagnosed as a benign stenosis of the pylorus, which had caused symptoms for three and one-half years, but the operation finally disclosed a round-celled sarcoma. There had been no signs of malignant growth; the general health had not suffered to any extent and the patient consented to an operation merely because she was tired of the occasionally necessary lavage of the stomach. Since the tumor was removed she has gained more than forty pounds.

92. **Mal Perforans as Late Result of Traumatic Injury of Sciatic.**—Sattler's two cases were men 56 and 28 years of age. The sciatic nerve had been completely severed, entailing paralysis of the limb. The latter gradually subsided with nearly complete restoration of motor function in the second case within two months and in six years in the first. Most of the sensory disturbances also gradually retrogressed.

93. **Pathognomonics of the Face.**—Wiesner reviews the various signs afforded by the appearance of the face in relation to various affections, allowing the latter to be differentiated by the specific changes in the facial expression, eyes, skeleton, etc. In regard to the risus sardonicus he states that it is liable to be induced by helminths and catarrhal conditions in the intestines, and also by irritation of the phrenic nerve from any affection of the organs it innervates. Some severe febrile affections, such as icterus gravis, yellow fever and pulmonary consumption, are distinguished by a blissful, smiling expression during great prostration. He describes the muscular mechanism for the changes noted in the face in tetanus and other affections.

95. **Tendon Grafting in the Thigh.**—Vulpius does not advocate tendon grafting except in case of flexion preventing the use of the limb. He disapproves of artificial tendons unless there are absolutely no natural tendon fibers to work with. If the silk is expelled later as a foreign body the result of the operation is lost. There are about 30 cases on record of grafting of the thigh tendons, to which Vulpius adds his experience of 20 cases, about 8 per cent. of his total of tendon-grafting operations. He illustrates several severe cases. In some all of the flexors and in others only part of them were transplanted in a single intervention which restored walking capacity. The more extensive the paresis the more complex the operations required, as in a case he illustrates in which the child had never used his flexed lower limbs at all. He had to lengthen the Achilles tendon by a plastic operation and graft a tendon in the leg. The left knee fixed in marked permanent flexion was treated by arthrodesis, the biceps transplanted forward, to prevent recurrence. The contracture in the hip joint was treated by myotomy, the bony fixed abduction remedied by subtrochanterian osteotomy. The right knee in flexed contracture was left movable. This was accomplished by transplanting the biceps, semitendinosus, semimembranosus

and sartorius forward and suturing them to the median and lateral margin of the patella. These interventions required three months, and now, fifteen months later, the boy can stand erect and walk with a cane out of doors and in the house without. He can flex his knee to 45 degrees, extension is perfect and with nearly normal strength. The plaster cast after tendon grafting is left for five weeks, during which the patient remains in bed. The after-treatment with massage, gymnastics, electrotherapy, etc., is not merely for the purpose of strengthening the muscles, but also to educate the corresponding nerve centers to their hitherto missing functions. He makes three lengthwise incisions, the first exposes the patella, its ligament and the quadriceps tendon. The second incision, back of the median condyle, opens up widely the sartorius, and its tendon is isolated and detached. The third incision is made to expose the tendon and belly of the biceps. The terminal tendon is detached and the belly of the muscle mobilized. From the lower end of the first incision a passage is made with a blunt instrument, beneath the fasciæ, through which the tendons are brought forward. As soon as the flexion is corrected the tendons are sutured side by side to the upper edge of the patella and from there downward near the median line as far as the patellary ligament, under moderate tension. The tendons must be fastened so as to act as nearly in a straight line as possible. The incisions are then completely closed; he never tampons.

96. Migraine.—Karplus thinks it important to distinguish between the genuine, inherited migraine and the merely symptomatic. For the former speak the appearance at an early age, the constancy of the recurrences and their similarity, and the family history. Genuine migraine is more frequent in women than in men, while paralysis and tabes are more frequent in the latter. In the treatment of genuine migraine removal of any pronounced source of peripheral irritation may have a favorable effect, as also all measures that tend to improve the general health, with avoidance of occasional causes and prophylactic doses of some sedative. It is possible that some drug to act on the vessels might be useful, but it would be dangerous to experiment during an attack. A prophylactic course of small doses of nitroglycerin or theobromin is theoretically justifiable during the intervals. Frequent and severe attacks of migraine probably contribute to deterioration of the walls of the cerebral blood vessels in time. A migraine subject is a chronically diseased patient and needs a certain amount of psychic treatment and tactful sympathy, too often neglected by the physician and rich in its rewards to charlatans.

100. Blue Light Treatment.—Kaiser gives illustrations of the apparatus for the production of blue light and of some of the patients whom he has treated by this means. He thinks that his experience with ordinary and erythematous lupus has established that the metabolism is powerfully stimulated by reflex action from the blue rays. The influence of these visible chemical rays is directly proportional to the distance and intensity of the light source. They penetrate blood-filled tissues readily and favor absorption, relieve pain and, when concentrated, induce actual anesthesia.

102. Phorxal, a New Blood Food.—Stichl has charge of the Mariagrün sanatorium near Gratz, and has been much pleased with the results attained with this new preparation of blood. He has administered it in 50 cases and found that it has a marked action on the blood, rapidly increasing the proportion of hemoglobin and improving the appetite and assimilation. The patients gained from 2 to 6 pounds a week in many instances after this tasteless powder was added to their food. There were no by-effects from its use, and he concludes by recommending it as a very inexpensive and efficient means of improving the composition of the blood in severe anemia and raising the vital energies of the nervous system in nervous dyspepsia, neurasthenia, hysteria, etc. He shows that in composition and mode of absorption it differs from other preparations of its kind.

105. Purpura Hemorrhagica.—In 3 of the 5 cases described the purpura developed independently, and in 2 others in connection with malaria; in one the hemorrhages seemed to appear vicariously in place of the intermittent febrile attacks. All were treated with lemons, six to ten a day, in the 2 last cases associated with Fowler's solution or aspirin. The lemon juice seemed to be promptly effective, although 2 of the idiopathic cases were extremely severe. One developed with a febrile bronchial catarrh and was followed by suppuration of a gland in each axilla. All are described in detail. No injurious by-effects were noted from the lemon treatment, although in large doses it had an evident laxative action. He mentions in conclusion that a popular remedy against malaria on the Roman Campagna is to stew lemons, sliced with the skin, and take the filtrate by the tablespoonful. He has repeatedly found this decoction beneficial in malarial dyspepsia.

113. Pseudo-Bulbar Paralysis.—This elaborate article by Hartmann is accompanied by 17 photogravures and a bibliography of 104 references. It is based on the study of 8 cases personally observed and analyzes the motor disturbances of this condition from every point of view with a long array of summarized conclusions.

114. Ochronosis.—Albrecht states that he knows of only 6 cases on record of this abnormal dark staining of the tissues, especially of the cartilages, first described by Virchow. He has recently observed a case in a man of 41, a consumptive, with melanuria and pigmentation of the ear. At the autopsy blackish gray or black spots were found throughout the vascular system, accompanying evidences of atheroma. The darkest spots were on the cartilages near the bones and in the joints, but the latter all appeared otherwise sound. Chemical tests showed that the pigmentation was not due to melanin nor to hematin or its derivatives.

116. Virulent Affections due to Pneumonia Bacillus.—The author of this article is Dr. Milan Sachs, whose tragic death from laboratory plague was recently reported. He described here a case of rapidly fatal infection with Friedländer's bacillus by way of the urethra, the prostate first invaded. An abscess formed which perforated into a vein, with resulting general infection, endocarditis, meningitis and multiple abscesses in the kidneys. The bacilli were found in the blood in enormous numbers.

119. Tumors of the Auditory Nerve.—Hartmann reviews 26 cases on record and 3 personally observed. The most pronounced type of the lesion is in cases with complete nerve deafness accompanied by all kinds of mild functional disturbances on the part of the organs occupying the posterior cranial fossa. The lesion first manifests itself by slowly encroaching nerve deafness, associated with slight dizziness, attacks of headache or paresthesia and pains in the trigeminus domain and possibly slight hemiataxia. Slowly progressive nervous deafness with one or more of these symptoms should suggest a tumor in the acustico-cerebellar space. Later choked disc becomes apparent, with motor and sensory disturbances in the extremities and finally disturbances in the functions of the other cranial nerves, predominating on the same side. A course of two to eight years may be anticipated, but early operation is justified by the precision with which the lesion can be located and the exceptional readiness with which the tumor shells out.

121. **Effect of Morphin on Gastric Secretion.**—The twenty articles in this souvenir number of the *Zeitschrift* are all by present or former pupils of Prof. J. W. Runeberg of Helsingfors, Finland. Holsti has studied the effect of morphin on the gastric secretion in 10 subjects. His general conclusion seems to be that the injurious influence of the drug is due more to its disturbing action on the motor function than to any influence on the secretion of gastric juice.

123. **Ectopic Kidney from Gynecologic Standpoint.**—In one of the 3 cases described one kidney was low in the small pelvis. In the second the left kidney was at the umbilicus and in the third a horse-shoe kidney was located very low, but the patient had borne four children. A number of cases of a congenital pelvic kidney obstructing delivery are on record. Even if the birth proceeds normally, the results may be disastrous from compression of the organ by the gravid uterus. Nephrectomy solely on account of interference with childbirth is not justifiable, and there are few instances on record where even restoration to normal position was attempted.

125. **Enterocystoma as Cause of Ileus.**—Krogius has observed a case of this kind and found records of 4 more in the literature. The age was 11 days to 62 years; all the patients were operated on, but all succumbed except one, 15 years old. His own patient was a two-months' infant.

126. **Pupil Aberrations.**—Schauman has noted a difference in the pupils in 723 subjects. The number includes 401 subjects, or 55.5 per cent., with no organic lesions but some neurosis, including 11 with exophthalmic goiter, 4 epileptics and 3 with chorea. In the remaining 322, or 44.5 per cent., there were organic lesions, including tuberculosis in 6.8 per cent. and some vascular affection in 5.5 per cent. When it is not due to an organic lesion it is therefore the expression of an asthenic diathesis or a sign of hereditary degeneracy. Jumping mydriasis is not so rare as generally supposed, he finds. He observed it in 11 cases, all with neuropathic manifestations from childhood. Hysteria was manifest in 3 or 4 and the others were not above suspicion. He does not regard it as a precursor of serious trouble.

127. **Transmission of Scarlet Fever in Milk.**—The milkmaid, a girl of 16, had been treated for a phlegmonous angina, and shortly afterward cases of scarlet fever developed in six families who were supplied with milk from this farm, and only two families with children on this milk route were spared. Two of the adults also suffered from a febrile tonsillitis at the same time. The facts observed suggest a genetic connection with the milk supply.

129. **Carbonic Oxid Poisoning.**—A young man was found unconscious five minutes after he had descended into a cistern in which a coke fire was burning. He recovered consciousness next day, but was totally blind and died in a month. The microscope showed lesions resembling those of a toxic, especially an alcoholic encephalitis. Sibelius remarks that the phenomena observed indicate that the toxic action of carbonic oxid is not essentially the driving out of the oxygen, but rather a primary toxic influence on the central nervous system.

130. **Ultimate Outcome of Tracheotomy.**—Pipping states that only 2 have become tuberculous out of his 67 patients on whom tracheotomy was done. His experience includes 82 cases since 1868. Seven of the patients have died. In 54 followed to date, 31 are free from disturbances of any kind, 20 have some trivial disturbances and one still has a fistula, one a chronic thickening in the right lung and a third is tuberculous, her father a consumptive.

132. **Round Ulcer in Finland.**—Round gastric ulcer is common all over the country, so that every physician averages about one to three cases a year. A collective inquiry among 79 physicians resulted in securing data in regard to 762 cases, including 5 children under 10, 369 women and 361 men. It seems to affect all classes indiscriminately. Traces of ulcer were noted in 2.29 per cent. of 3,577 cadavers, and ulcer was treated in 1.74 per cent. of 11,850 patients at the clinic.

134. **Albumin Metabolism in Pernicious Anemia.**—Rosenqvist's article fills 128 pages and contains detailed bibliographic notes. It is based on a study of the metabolism in 20 cases of anemia due to the bothriocephalus and to a number of cryptogenetic cases of pernicious anemia. In both cases there is a destruction of albumin, manifestly of a toxic nature, and in both there are evidences of phenomena of immunization in time. The destruction of albumin is more constant in the anemia due to the bothriocephalus, and it persists for a time after expulsion of the latter. In both forms of anemia there is also at times an exaggerated elimination of the endogenic purin bodies, a probable indication of exaggerated destruction of nucleated tissues.

135. **Pathogenic Action of Balantidium Coli.**—Ehrnrooth has not found evidences of degenerative or inflammatory processes elsewhere than in the gastrointestinal tract and there they were unmistakably of mechanical origin. Neither the blood nor the organs suggest intoxication from the presence of the balantidium coli. He describes a case in detail, a woman of 52, who for twenty years had suffered from vomiting and abdominal pains.

137. **Rigid Spine.**—From the autopsy of a case and reports of five others Siven has become convinced that this disease is an inflammation of the joints entailing finally complete ossification of the smaller spinal articulations, a chronic ankylopoietic arthritis. The process differs from that of general arthritis deformans.

138. **Casein Enemata.**—Proton is a patented preparation of milk casein. Mixed with milk it forms an excellent material for nutrient enemata, readily absorbed and containing a large proportion of albumin and phosphorus.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

TWENTY-SECOND ANNUAL MEETING OF THE HAMOT HOSPITAL ASSOCIATION, with Reports of Managers and Officers, 1902. Paper. Pp. 71. Erie, Pa.: Herald Printing and Publishing Company. 1903.

A MANUAL OF SURGICAL TREATMENT. By W. Watson Cheyne, C.B., M.B., F.R.C.S., F.R.S., Professor of Surgery in King's College, London, and F. F. Burghard, M.D., M.S. (London), F.R.C.S., Teacher of Practical Surgery in King's College, London. In Seven Volumes. Volume VII. The Treatment of the Surgical Affections of the Rectum, the Liver, Pancreas and Spleen, the Genito-urinary Organs, the Breast and the Thorax. Cloth. Pp. 559. Price, $5.75 net. Philadelphia and New York: Lea Brothers & Co. 1903.

SURGICAL DISEASES OF THE ABDOMEN, with Special Reference to Diagnosis. By Richard Douglas, M.D., Formerly Professor of Gynecology and Abdominal Surgery, Medical Department, Vanderbilt University. Illustrated by 20 Full-page Plates. Cloth. Pp. 883. Philadelphia: P. Blakiston's Son & Co. 1903.

INDEX-CATALOGUE OF MEDICAL AND VETERINARY ZOOLOGY. Part 3. (Authors C to Czygan.) By Ch. Wardell Stiles, Ph.D., Consulting Zoologist of Bureau of Animal Industry, and Albert Hassall, M.R.C.V.S., Acting Assistant Zoologist of Bureau of Animal Industry. Paper. Pp. 324. Washington: Government Printing Office. 1903.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. A., under orders from the Adjutant-General's Office, Washington, D. C., for the week ending June 20, 1903:

Bosley, John R., contract surgeon, will proceed from Washington, D. C., to Governor's Island, N. Y., and report to the commanding general, Department of the East, for assignment to duty.

Field, Peter C., first lieut. and asst.-surgeon, is granted an extension of fifteen days' leave.

Shortlidge, Edmund D., first lieut. and asst.-surgeon, having completed the duty for which he was ordered to Washington, D. C., June 3, will rejoin his proper station at the U. S. General Hospital, Presidio.

Straub, Paul F., captain and asst.-surgeon, on the expiration of his present leave is directed to proceed to Camp Monterey, Cal., for duty.

Wilson, Roy A., contract surgeon, is granted leave of absence for two months.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending June 27:

Medical Inspector H. E. Ames, commissioned medical inspector from Jan. 20, 1903.

Surgeon C. F. Stokes, detached from the Navy Yard, League Island, and ordered to the Bureau of Medicine and Surgery, Navy Department.

Surgeons C. D. Brownell, S. G. Evans, C. E. Riggs, M. K. Johnson, W. B. Grove, E. O. Huntington, commissioned surgeons from March 3, 1903.

P. A. Surgeon H. E. Odell, commissioned P. A. Surgeon from Nov. 8, 1902.

Asst.-Surgeon J. J. Snyder, detached from the Naval Hospital, Philadelphia, and granted sick leave.

Asst.-Surgeon W. W. Verner, ordered to the Naval Hospital, Philadelphia.

Surgeons W. M. Wheeler, L. Morris, F. T. Pleadwell, C. P. Kindleberger and F. C. Cook, commissioned surgeons from March 3, 1903.

Surgeon G. Pickrell, detached from the *Iowa* and ordered to wait orders.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended June 25, 1903:

Surgeon J. M. Gassaway, granted leave of absence for two days from June 7.

Surgeon Eugene Wasdin, granted leave of absence for three days from June 20.

Surgeon S. D. Brooks, granted leave of absence for one day, June 22.

Surgeon J. H. White, granted leave of absence for one month from July 2.

Surgeon P. M. Carrington, granted six days' leave of absence under Paragraph 189 of the regulations from June 20, 1903; granted extension of leave of absence for seven days.

P. A. Surgeon G. B. Young, granted leave of absence for two months from July 7.

P. A. Surgeon E. K. Sprague, leave of absence for seven days from June 4, 1903, granted under Paragraph 191 of the regulations, amended so as to be for four days only. Relieved from duty at Fort Stanton, N. M., and directed to proceed to Calcutta, India, for duty in the office of the U. S. Consul-General.

P. A. Surgeon S. B. Grubbs, granted extension of leave of absence for seven days from June 23.

Asst.-Surgeon M. K. Gwyn, to report to Asst.-Surgeon V. G. Heiser, recorder of board of examiners, Manila, P. I., on August 8, 1903, for examination to determine his fitness for promotion to the grade of passed asst.-surgeon.

Asst.-Surgeon W. C. Hobdy, to report to P. A. Surgeon L. E. Cofer, recorder of board of examiners, Honolulu, H. I., on August 15, 1903, for examination to determine his fitness for promotion to the grade of passed asst.-surgeon.

Asst.-Surgeon B. H. Earle, granted leave of absence for seven days from June 25.

A. A. Surgeon Bready, leave of absence for three days granted by Bureau letter of June 6 revoked.

A. A. Surgeon B. Y. Harris, granted leave of absence for thirty days from July 22.

A. A. Surgeon C. B. Sweetin, granted leave of absence, on account of sickness, for thirty days from June 10.

Pharmacist G. W. Iltis, to report to P. A. Surgeon W. G. Stimpson, chairman of board of examiners, San Francisco, on June 29, 1903, for the examination to determine his fitness for promotion to the grade of pharmacist of the second class.

BOARDS CONVENED.

Board convened at Washington, D. C., June 25, 1903, for the preparation of sketch plans and memoranda relative to a hospital building at Ellis Island, N. Y. Detail for the board: Assistant Surgeon General L. L. Williams, chairman; Assistant Surgeon General W. J. Pettus; Surgeon G. W. Stoner; P. A. Surgeon J. C. Perry, recorder.

Board convened at San Francisco, June 29, 1903, for the examination of Pharmacist G. W. Iltis, to determine his fitness for promotion to the grade of pharmacist of the second class. Detail for the board: P. A. Surgeon W. G. Stimpson, chairman; Asst.-Surgeon C. W. Vogel, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended June 27, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, June 13-20, 3 cases.
California: San Francisco, June 7-14, 1 case.
Colorado: Denver, May 23-June 6, 24 cases.
Georgia: Atlanta, June 3-17, 3 cases.
Illinois: Belleville, June 13-20, 3 cases; Chicago, June 6-20, 6 cases, 1 death; Danville, June 6-13, 1 case.
Indiana: Indianapolis, June 6-20, 3 cases; Kokomo, June 13-20, 1 case.
Iowa: Des Moines, June 13-20, 1 case.
Louisiana: New Orleans, June 13-20, 2 cases.
Maine: Fort Kent and vicinity, June 18, 9 cases.
Maryland: Cumberland, May 1-31, 24 cases, 4 deaths.
Massachusetts: Fall River, June 6-20, 7 cases.
Michigan: Detroit, June 15-22, 7 cases; Flint, June 13-20, 1 case; Grand Rapids, June 13-20, 2 cases; Port Huron, June 13-20, 10 cases.
Minnesota: Winona, June 13-20, 1 case.
Missouri: St. Louis, June 7-21, 18 cases.
New Hampshire: Manchester, June 13-20, 2 cases; Nashua, June 13-20, 1 case.
New York: Elmira, June 13-20, 3 cases.
Ohio: Cincinnati, June 12-19, 7 cases; Cleveland, June 6-13, 1 case; Dayton, June 13-20, 2 cases; Hamilton, June 13-20, 3 cases; Toledo, May 30-June 13, 8 cases, 1 death; Warren, June 13-20, 1 case.
Pennsylvania: Carbondale, June 7-21, 4 cases; McKeesport, June 6-20, 1 case; Pittsburg, June 6-20, 40 cases, 4 deaths, 1 case imported; Philadelphia, June 13-20, 35 cases, 4 deaths.
Tennessee: Memphis, June 13-20, 2 cases; Nashville, June 13-20, 1 case.
Utah: Salt Lake City, June 6-20, 18 cases.
Washington: Tacoma, June 15-22, 1 case; Whatcom, Jan. 1-June 1, 14 cases, 2 deaths.
Wisconsin: Milwaukee, June 13-20, 10 cases.

SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, March 1-31, 8 deaths.
Austria: Prague, May 30-June 6, 4 cases.
Belgium: Antwerp, May 30-June 6, 3 cases, 1 death; Ghent, May 16-June 6, 4 deaths; Liege, May 23-30, 1 case, 1 death.
Brazil: Bahia, May 23-30, 2 cases; Rio de Janeiro, May 10-27, 7 deaths.
British Guiana: Domerara, Feb. 10-May 16, 344 cases, 2 deaths.
Canada: Hamilton, June 6-13, 1 case; Ontario, April 1-30, 122 cases, 2 deaths; Vancouver, May 1-30, 1 case.
Canary Islands: Las Palmas, May 18-June 6, 37 cases.
Colombia: Bocas del Toro, June 2-9, 4 deaths.
Germany: Strassburg, April 1-30, 13 cases.
Great Britain: Birmingham, May 30-June 13, 9 cases; Bristol, May 30-June 6, 1 case; Dublin, May 30-June 6, 15 cases, 3 deaths; Dundee, May 30-June 6, 1 case; Leeds, May 30-June 6, 40 cases; Liverpool, May 30-June 13, 81 cases, 5 deaths; London, May 30-June 6, 24 cases; Manchester, May 23-June 6, 20 cases, 4 deaths; Nottingham, May 23-30, 2 cases; Newcastle-on-Tyne, May 30-June 6, 2 cases; Sunderland, May 30-June 6, 2 cases.
India: Bombay, May 19-26, 45 cases.
Japan: Kobe, May 9-16, 2 cases; Yokohama, May 16-23, 1 case.
Mexico: City of Mexico, May 31-June 7, 24 cases, 14 deaths.
Russia: Moscow, May 23-30, 8 cases, 1 death; Warsaw, May 16-23, 1 death.
Spain: Cadiz, May 1-31, 1 case.
Straits Settlements: Singapore, April 11-18, 4 cases.
Turkey: Smyrna, April 19-26, 1 death.
Uruguay: Montevideo, March 1-April 5, 22 cases.

YELLOW FEVER.

Brazil: Rio de Janeiro, May 10-24, 12 deaths.
Colombia: Panama, June 8-15, 3 cases, 1 death.
Costa Rico: Limon, June 4-11, 4 deaths.
Mexico: Coatzacoalcos, May 30-June 6, 1 case; Tampico, June 6-13, 11 cases, 8 deaths; Vera Cruz, June 6-20, 57 cases, 17 deaths.

CHOLERA.

India: Bombay, May 19-26, 1 death; Calcutta, May 16-23, 71 deaths.
Straits Settlements: Singapore, April 11-18, May 8-16, 30 deaths.

PLAGUE.

Australia: Brisbane, April 11-May 9, 5 cases.
Brazil: Rio de Janeiro, May 10-24, 2 deaths.
India: Bombay, May 19-26, 255 deaths: Calcutta, May 16-23, 47 deaths; Karachi, May 17-24, 136 cases, 127 deaths; Mauritius, May 14-21, 2 cases.

Published under the Auspices of the Board of Trustees

VOL. XLI. CHICAGO, ILLINOIS, JULY 18, 1903. No. 3.

Addresses.

NEUROLOGIC PROGRESS AND PROSPECTS.

CHAIRMAN'S ADDRESS, DELIVERED BEFORE THE SECTION ON NERVOUS AND MENTAL DISEASES OF THE AMERICAN MEDICAL ASSOCIATION, AT THE FIFTY-FOURTH ANNUAL SESSION, HELD AT NEW ORLEANS, MAY 5-8, 1903.

F. W. LANGDON, M.D.
CINCINNATI.

INTRODUCTORY.

Mankind in general and practitioners of the healing art in particular may be likened to the different groups of dwellers in a series of narrow and deep valleys surrounded by lofty mountains. Each ordinarily obtains a restricted view of his own valley and sees little or nothing of the others. When by chance or intent they meet on an eminence, which is far above all their natural habitats, their view is not only broader and more accurate as concerns their own individual valleys, but extends in varying degrees over the domains of others.

So it is with the members of our guild, when they rise to a higher intellectual plane at meetings such as this; their respective views broaden and tend to harmonize with those of their fellows, while at the same time the aggregate of their fields of mental vision is vastly augmented.

The general practitioner surveys the domain of the specialist, getting here and there an idea, while the specialist broadens his horizon by contact with the generalist and by a more comprehensive view of the work of his confrères.

GENERAL CONSIDERATIONS.

The classic observations of Broca[1] (1861), establishing a definite cerebral location for the function of articulate speech, were followed up so assiduously, during the next three decades, by numerous investigators, that the period named may be termed the era of gross localization of nervous functions. In marked contrast with that period the past decade may be fitly characterized as an era of progress in knowledge of structural organization of the nervous system.

The biologic law that function precedes and determines structure is here paralleled in the sense that knowledge of function has preceded and led up to knowledge of intimate structure.

Beginning with the demonstration by Cajal[2] (1893-94) of the anatomic individuality of the neuron, the labors of a host of enthusiastic investigators throughout the civilized world have rendered the decade now closing a most memorable one in neurologic progress.

The histologic, physiologic and pathologic fields have been lighted up as never before. A new terminology has been necessitated by the newer knowledge of neuronic architecture of the nervous system; and we find, in consequence, the older terms: areas, masses, nuclei, fiber tracts and reticulum, replaced largely, or at least added to and elucidated, by "neuron," axon, dendrite, collateral process, gemmule, etc.

As one result of all this labor and progress our present-day conceptions of the real nature of many diseases of the nervous system are in marked contrast with those of a former era. To none is this more apparent than to the practitioner, who compares his modern text-books and the literature produced at such gatherings as this with the same sources of information of a decade or more ago.

That this knowledge of intimate structure as related to function, both physiologic and pathologic, is still progressing at a rapid rate is a matter for profound congratulation, since its obvious tendency is to furnish an increasingly definite foundation for the more successful application of therapeutic measures. A second result may be observed in the rather more optimistic views as to the possibilities of prophylaxis and therapy in diseases of the nervous system which pervade the modern neurologic mind.

NEUROLOGIC PROGRESS.

During the past year the progress of neurologic medicine has been satisfactory, though not marked by brilliancy of achievement.

No supreme discovery or demonstration approaching in importance that of "the neuron" has been announced. Yet a steady advance has been kept up along the "firing line," and the skirmishers, represented by the workers in research laboratories, have penetrated farther than ever into the territory of the heretofore unknown with noticeable advantage to the position and strength of the "main army."

While "the neuron" maintains its position as a "star of the first magnitude" in the neurologic firmament, its lustre has been perhaps a trifle dimmed by the observations of Bethe and of Ballance and Stewart on "The Healing of Nerves."[3] Briefly, these appear to affect the neuron doctrine as follows:

1. They indicate that destroyed axis cylinders of peripheral nerves are reproduced, not by down growths from the proximal ends of the cut or degenerated axons, but by proliferation of neurilemma cells of the separated portions of the axis cylinder.

2. These observations also indicate that a peripheral axon (axis cylinder) is not originally a mere outgrowth from a single spinal neuron body (nerve cell), but is a result of the fusion of a chain of cells, the prototypes or

equivalents of other chains represented in the neurilemma.

3. When the axon is destroyed the remaining neurilemma cells take up the task of producing a new one by proliferation and end-to-end fusion of new cells.

Two facts stand out prominently in this connection. First, that these observers admit that development is more or less incomplete unless the newly reproduced distal segment is eventually joined to the proximal end; another illustration of the law that structure is dependent on function.

It will also be noted that these observations apply to peripheral neurons only, and do not in any way affect the status of the central neurons, since their axis cylinders are devoid of neurilemma, and hence must apparently depend on their neuron bodies for trophic influence. Moreover, reproduction of these central axons when once destroyed is almost unknown, only a few observations on the subject existing in the literature (Worcester).[4]

The painstaking and admirable observations of Apáthy,[5] extending over a period of fourteen years and published some six years ago, were claimed by him to show that the entire nervous system is permeated by a network of ultimate fibrillæ passing unbroken through the neurons. They have been in part accepted by Bethe and Nissl, who also consider that the resulting "fibrillary hypothesis" invalidates the neuron doctrine. As these fibrillæ themselves, according to Apáthy's showing, are a product of certain neuron bodies (cells), the conclusion that they are of secondary importance only seems justified at present.

Far from disproving or supplanting the neuron doctrine the "fibrillary hypothesis" of Apáthy seems to the writer to have merely attained the dignity of an appendage to it; an appendage, doubtless of considerable import, it is true, but just how important remains to be determined by its verification in a larger series of organisms than earthworms and leeches.

NEURODYNAMICS.

The nature of nerve force and the conditions of its transmission yet remain an unopened book, of which Professor Loeb[6] has essayed to exhibit to us the title page in his ingenious application of the electro-chemical theory of ions to the dynamic processes of the neuron and muscle cell.

The main landmarks of his hypothesis may be briefly stated as follows:

1. An ion is the electrolytic representative of an atom, but is, theoretically, much smaller in size.

2. Ions, like the electrolytes of which they are the ultimate electrical units, are positive or negative, hence anions and kations.

3. Their function, by their presence in definite proportion in each tissue, is to preserve the "labile equilibrium" of the colloid materials of protoplasm on which its activities depend.

4. Variations in these proportions or attempts to restore the same to normal (through electro-chemical action) give rise to function in the particular tissue that is the seat of such variation at any given time.

5. Hence, the dynamic process of neurons, as of muscle cells, may depend on the proportions of ions of, say calcium, sodium, potassium, etc., that are present at any particular instant.

6. This, if verified, would apparently indicate that the dynamics of function reside in the ions, while the quality and direction of function only are conditioned by the histologic structure and connections of the neuron.

Dercum[7] and others have proposed, some years ago, a theory of "amœboid protrusion and retraction" of neuron processes (gemmules) in order to account for the "make" and "break" of function in physiologic as well as pathologic (functional) states; accounting in this way for sleep and other suspensions of consciousness, as well as for various paralyses of functional character.

While this idea has probably served a good purpose in directing attention to changes in the neuron, as the basis of function, yet the type and nature of the movement referred to is obviously too gross in character to satisfy the demands of the problem.

The bearing of the theory of ions, however, is quite another matter. It is much easier to conceive of an alteration in electro-chemic status as the basis of changes in nervous function than to attribute them to so coarse a process as physical retraction and elongation.

In fact, in commenting on this topic it has been the custom of the writer to say to his classes that, while the theory of physical retraction and expansion is not tenable in this connection, yet it is quite conceivable that a break in chemical relations, a chemical retraction and reapproachment, so to speak, might account more satisfactorily for the facts. The same may be said of an alteration in electro-chemical status, due to variations in ions.

PSYCHODYNAMICS.

The impression that "psychic" activity may exist independently of physical agents still appears to obtain a hold even on some medical minds, and is not confined to the devotees of the various so-called "cults" patronized by the laity and exploited by charlatans.

It seems hardly necessary to say that such independent existence of "psychic" activity has not been demonstrated in fact, and in the nature of things is not likely to be.

CLINICOPATHOLOGIC.

Pellagra has been demonstrated by Ceni[8] in a remarkably complete series of experiments, to be due to infection by micro-organisms belonging to the mould fungi, namely, the *Aspergillus fumigatus* and the *Aspergillus flavescens*. Either species may act in any given case, but seldom both.

These organisms reach the human subject through the medium of infected maize, but are also observed in mouldy bread, etc.

The parasites pass from the intestine in the form of spores, become localized in various tissues and organs (lungs, pleura, pericardium and pia-mater), and there elaborate and emanate very virulent toxines, which give rise to phenomena of general poisoning, as well as to local inflammatory process of a diffuse character.

The nervous symptoms which have led to the classification of pellagra as a nervous disease consist of widespread alterations in sensation, motion and intellect.

Thermalgesia along the spine, numbness and formication of the legs.

Tremor, motor inco-ordination and paraplegic weakness are common.

Apathy, incoherence and melancholic symptoms are noted.

The mortality is high, but recoveries do occur. The importance of the discovery is evident when we realize that: 1. Sixty thousand persons suffer from the disease in Italy alone at the present time. 2. By reason

of the fact that the author has devised a plan for the successful treatment of the disease by the serum of immunized goats and horses.

Although limited, so far as known, to Italy and southern France, in which countries it is traceable to the use of unripe and badly kept maize as a food, the disease interests us for three reasons:

1. It affords an example of a distinct neuron degeneration due to a definite organism.

2. The symptoms, strongly suggestive in some cases of ataxic paraplegia (combined sclerosis), in others of paresis, and in others of ankylostomiasis (Harris[9]), may call for differentiation from those affections in this country.

3. Owing to the well-known occasional presence of the aspergillus in the auditory canal, where it has heretofore been considered an object of local rather than of general pathologic import.

MYELITIS.

Acute myelitis, so-called, is one of the diseases of which our knowledge of the pathologic nature is being gradually developed.

The older idea that the inflammation was the primary factor, the vascular disease and softening secondary, has been practically reversed in a large proportion of the cases, thus bringing the subject in line with similar processes in the brain, where the vascular disease (endarteritis and thrombosis) has long been recognized as the primary element in acute softening.

Singer,[10] in a valuable résumé of the subject, reports two autopsies, both showing obliterative arteritis of syphilitic origin, and refers to nineteen others, fifteen of which presented a syphilitic history. His conclusions are:

1. So-called acute myelitis is found on microscopic examination, in the majority of recorded cases, to be not inflammatory, but due to thrombosis of spinal vessels.

2. That by far the most common cause of this thrombosis is syphilitic arteritis, and that senile arterial degeneration forms a considerable proportion of the remaining cases.

3. This view as to the pathology is confirmed clinically by the analogy between this disease and cerebral thrombosis.

Williamson,[11] in 1894, advocated the same views, which are now accepted to a greater or less extent by Gowers, Oppenheim, Marie, Dana, Church and Peterson, though Singer, as above quoted, takes a rather more advanced stand as to the comparative frequency of thrombosis as a cause. A somewhat extensive clinical experience leads the writer to heartily indorse these views of Singer, the bearing of which on our therapy is obviously of great practical importance.

BRACHIAL NEURITIS.

Somewhat analogous to the problems presented by acute myelitis are those relating to the pathology of brachial neuritis, especially of those of uni-radicular type.

E. Farquhar Buzzard,[12] in an important article in *Brain*, reports six carefully worked-out cases, and suggests that vascular lesions, embolic or thrombotic, better explain these cases than the older idea of a neuritis of toxic or "exposure to cold" origin. His conclusions are as follows:

1. "There exists a clinical group of cases in which the symptoms (localized muscular atrophy in shoulder, arm or hand muscles, sensory dissociation and hypesthesia) strongly suggest a more or less complete destruction of functional continuity in one of the spinal nerves forming the brachial plexus.

2. "The objective disturbances of sensibility resulting from this lesion closely conform with those observed by Sherrington after cutting a posterior root in a monkey. They differ in some respects from the anesthesia produced by the division of a peripheral nerve. The objective hypesthesia is not associated with any subjective sensation of numbness, and is consequently overlooked by the patient.

5. "The atrophy of the affected muscles is in excess of what might be expected in view of the fact that many of the muscles receive fibers from two or more spinal nerves.

6. "The condition generally occurs in persons who have at some time been the subjects of a disease affecting the cardio-vascular system. The morbid process is probably vascular in character and may be sudden or gradual in its onset."

PACHYMENINGITIS HEMORRHAGICA INTERNA.

Barratt[13] records an exhaustive series of investigations on man and lower animals, the results of which indicate that intravascular thrombosis is the probable essential lesion leading to the formation of the so-called false membrane in this disease He concludes: "Finally, the view may be advanced that pachymeningitis interna hemorrhagica is a morbid process in which the essential lesion is a separation of fibrin, usually within the blood vessels, on which the other changes in this condition are largely if not chiefly dependent." The article is well illustrated.

LOCAL PANATROPHY.

Sir William Gowers[14] contributes a brief but interesting article under this title.

"In certain areas of the trunk, limbs or face, which vary in diameter from that of a nut to that of an orange, or larger, there seems to be wasting of all the subcutaneous tissues down to the bones, with slight change in the skin, which is then distinctly thinner and slightly discolored. The aspect of the areas may be described as that of a subcutaneous excavation." Even the bones may be affected. The distribution is without definite relation to the muscles or nerve distribution. No hypothesis is advanced as to its cause.

BLOOD CHANGES IN EPILEPSY.

Pugh[15] contributes an important article "On Certain Blood Changes in Idiopathic Epilepsy," based on an investigation of forty cases. His conclusions are:

1. The alkalinity of the blood (in epileptics) in the interparoxysmal period is lower than the average of the control cases.

2. The diminution is gradual and progressive, and is more marked in those cases suffering from gastric catarrh and constipation.

3. There is a marked sudden and pronounced fall immediately prior to the onset of the fit.

4. There is a further fall in the alkalinity after the fit is over; this diminution is seen from three to ten minutes after the attack.

5. This after-diminution depends on the duration and severity of the muscular twitching and on the degree of the alkalinity in the inter-paroxysmal period.

6. There is a gradual return of the blood to its normal alkalinity, which takes place in five to six hours, the rise being more marked in the first hours.

7. If the alkalinity keeps at a low value it may determine the onset of another fit.

8. The diminution after the fit is due to the chemical end products of muscular metabolism, i. e., sarcolactic and carbonic acids and not to substances in direct relation to the epilepsy.

9. The diminution after a nocturnal fit takes a longer time to return to the normal than the diminution after a day fit.

10. It is impossible to elevate and maintain the alkalinity within physiological limits for any appreciable length of time by the administration of drugs.

11. There is a leucocytosis after a fit. The increase is due to the small hyaline cells, also to a less extent to the large hyaline cells. The polymorphonuclear cells are diminished. There is an increase in the eosinophile cells some hours after the attack.

12. The leucocytosis is not so pronounced in *status epilepticus;* it diminishes with each seizure.

Respecting treatment the author remarks: "The effect of drugs on the alkalinity is transient, and it is impossible to elevate and maintain the alkalinity within physiological limits for any appreciable length of time. The bromides elevate the alkalinity even to the normal of the control cases for a certain time, but on continued administration, and even when the dose is increased, the alkalinity fails. The best results were obtained from strontii bromid, sodi bicarb, aa: gr. 15 *ter in die;* for some time the alkalinity was maintained at a high value, but only to fall again. Suprarenal extract has apparently little effect on the alkalinity. The effect on the mental state was good, and all the patients subjected to the treatment recovered from their mental confusion much sooner."

One case escaped the headache usually following the fits.

"In all the cases the number and frequency of the fits were much increased, and on this account the suprarenal treatment was stopped. These results are very different from those obtained by Dr. Hill,"[16] who reports improvement from the use of suprarenal therapy, both as regards the mental state and the frequency of the attacks.

SYMPTOMATOLOGY—CEREBRAL LOCALIZATION.

Phelps,[17] from a study of brain injury and disease, reinforces the view of Bianchi,[18] that the frontal lobes are the seat of the "psychic" functions proper, and particularly advocates that the left prefrontal region is especially concerned in mental processes.

X-RAY LOCALIZATION.

Charles K. Mills[19] reports a case of brain tumor localized by the *x*-ray, which confirmed the clinical diagnosis, being the second instance of this nature, the first being by Church.[20]

Gould[21] contributes a critical study of DeQuincey, Carlyle, Darwin, Huxley and Browning, as regards the cause of their chronic ill health. His conclusions, supported by arguments that are well worth consideration by the neurologist, are, that the opium habit of De Quincey, the ill-temper and dyspepsia of Carlyle, the neurasthenia of Darwin and the headaches of Huxley and Browning were all due to eyestrain, and could have been avoided by resort to modern methods for the detection and correction of errors of refraction.

LUMBAR PUNCTURE.

The usefulness of this procedure as a diagnostic aid has been extended to surgical diagnosis by Tuffier (vide Hughes[22]), who suggests that a blood-stained cerebrospinal fluid means vertebral fracture.

Monod[22] has found leucocytosis of the cerebrospinal fluid in locomotor ataxia and in general paresis, but "nothing significant" in alcoholism hysteria, hemiplegia or neuritis.

REFLEXES, ETC.

Babinski has enriched our list of clinically available signs by the addition of five within about as many years. Some of these are so little known in America, generally speaking, that brief reference to them here may not be amiss.

1. The "Babinski sign"[23] proper, or the "toe sign," is a reflex extension of the great toe in response to mild plantar irritation. This sign continues to hold its own as a most reliable indicator of organic disease of the "pyramidal" tract. The normal plantar reflex is a flexor movement of all the toes.

2. The achilles tendon reflex is a plantar flexion of the foot at the ankle joint, following a tap on the tendo-achilles. The patient, during this procedure, kneels on a chair or lounge with the feet hanging over its edge. The response (plantar flexion of ankle) is weakened or absent in true sciatic neuritis and in tabes. It may be absent early in tabes where the knee-jerks are not yet lost. (Bramwell, *Brain,* 1901, 554.)

3. The sign of "combined flexion of the thigh and trunk."[24] To investigate this reflex the patient is placed on his back on a horizontal surface with arms folded across his chest. He is then asked to assume the sitting posture without using his hands. In a hemiplegia of organic origin this effort is accompanied by a raising of the paralyzed limb, which is flexed at the thigh but extended at the knee. In a functional (or so-called hysterical) hemiplegia the paralyzed limb remains flaccid and parallel with the sound one.

4. The "platysma sign"[24] of Babinski is obtained by asking the patient to forcibly open the mouth against the resistance of the investigator's hand placed beneath the chin, or by asking him to flex the head on the neck while the operator applies resistance to the forehead. In either case the platysma contraction is absent or lessened on the paralyzed side in organic paralysis, while there is no difference in the two platysma contractions in a functional hemiplegia.

5. The sign of "exaggerated flexion of the forearm."[24] This is due to hypotonicity of the muscles by reason of which a greater degree of flexion is permitted on the paralyzed side in recent organic paralysis. In functional paralysis the hypotonicity is absent and the degree of flexion similar on both sides. Babinski remarks of this sign: "Since the phenomenon may occur to a slight extent in health, it is of value when it is very decided."

THE SUPRA-ORBITAL REFLEX.

This reflex, as described by McCarthy,[25] is obtained by tapping, with the finger or a light hammer, over the trunk of the supra-orbital nerve on the forehead. The normal response is a contraction of the lower eyelid. The presence of this response is evidence of integrity of the fifth and seventh cranial nerves. The reflex is present in central lesions involving motion or sensation of the face; absent in peripheral lesions of the fifth and facial nerves. It is important that the observer stand behind the patient in testing for this reflex, so as to avoid the involuntary winking due to visual-motor reaction.

THE LIP REFLEX OR "MOUTH PHENOMENON" OF NEWBORN CHILDREN.

While referred to briefly by Loos, 1896, and Escherich, 1898, Thomson[26] has given us a fuller and well illus-

trated account of this reflex, which has received little attention heretofore. It would appear to be one of the most fundamental organic reflexes which is essential to the very existence of the species, consisting as it does of a protrusion of the lips, and in some instances of sucking movements, brought out by tapping the upper or lower lip near the angle of the mouth. It occurs in all healthy newborn infants when they are asleep, according to Thomson. It seems to be exaggerated in infants who are taking chloral or who are having or about to have convulsions.

OPPENHEIM'S REFLEX.

If the inner side of the leg be stroked firmly from above downwards with the handle of a percussion hammer (or other blunt firm instrument) along the posterior border of the tibia or a little posterior to it, commencing about a hand's breadth below the knee and going downwards nearly to the ankle, the result in healthy individuals and in cases of functional nervous disease is either negative or it produces a plantar flexion of the toes.

In lesions of the pyramidal tract there is an extension of the toes and abduction or adduction of the ankle.

Oppenhein[27] is of the opinion that this reflex is not identical with Babinski's "toe sign," inasmuch as it is often present in cases of spastic paresis where Babinski's reflex is doubtful; moreover, it does not occur in the small proportion of healthy persons who exhibit the Babinski reflex; finally, the involvement of the tibialis anticus and occasionally of the peroneus is another point of difference from the phenomenon of Babinski.

ANKLE CLONUS.

Wier Mitchell[28] calls attention to the fact that the motor element of ankle clonus is manifested through the soleus muscle alone, the gastrocnemius taking no part on account of its relaxed state due to its femoral attachment.

THERAPY—HYSTERIA AND NEURASTHENIA—REST TREATMENT.

Dejerine[29] reports two hundred severe cases of this class treated by the Wier Mitchell plan of isolation, milk diet and rest, but without massage. He had only two failures. The treatment is also emphatically indorsed by the reviewer (Alexander Bruce).

We have heard so much of the "rest" treatment of neurasthenia since its introduction to the profession by Dr. S. Wier Mitchell, some years ago, that it is a trifle refreshing, to say the least, to find the pendulum swinging to its antithesis, the "work" cure.

A group of contributors on the subject are noted: Pearce (massage), *Internat. Med. Jour.*, 1902-03; Sinkler, Hydrotherapy, *Milwaukee Med Jour.*, 1901; Pearce, F. S., *Alienist and Neur.*, 1902, p. 259; Schwab, S. I., *Interstate Med. Jour.*, 1902, 248.

A pertinent query in this connection would appear to be: Have we not been a little too liberal in the application of the term "neurasthenia" as we were with "hysteria" until within a few years?

It is not possible that we apply the term neurasthenia —which should be literally translated, simple dynamic weakness due to lowered vitality—to a large group of affections characterized by "irregularity in function," or "lack of balance" in dynamogenesis.

In such cases a transfer of function is the logical method, and here the "work cure" finds its place. True exhaustion, it appears to the writer, must still call for rest.

RAYNAUD'S DISEASE.

Cushing[30] advocates "treatment by the tourniquet" to counteract the vaso-motor spasm of Raynaud's disease. The case reported (in a woman of 35) was a severe one, with decided arterial spasm and great pain, accompanied by a local asphyxia of all the digits, with almost daily exacerbations. Superficial gangrene of one or more of the toes or fingers occurred on several occasions.

"On Nov. 10, 1900, during an exacerbation of pain and asphyxia chiefly affecting the left upper extremity, the flat rubber bandage was first employed as a tourniquet about the upper arm. Its application caused considerable local discomfort and pain referred to the side of the thorax (inter costohumeral?)

"On its removal, after one or two minutes' application, a bright flush of the extremity followed, with increase of surface temperature and a much more readily palpable radial artery. The vaso-motor relaxation lasted only a short time, but the patient expressed a sensation of considerable relief. From this time seems to date the beginning of her improvement.

"The tourniquet was applied daily to one or another member according as the symptoms indicated.

"The application was finally extended to periods of five minutes or longer.

"The relief to the burning pain was so pronounced that after the first few trials the patient was not only very willing to submit to the temporary discomfort of constriction, but would call for it."

Serum therapy continues to hold out hopes to the neurologist. Its use in pellagra by Ceni[7] has been already alluded to.

Bruce,[31] after a trial of serum treatment in paresis, concludes as follows:

1. "General paralysis is a disease directly due to poisoning by the toxins of bacteria, the point of attack of which is through the gastric and intestinal mucous membrane.

2. "The poisoning is probably a mixed poisoning, but the bacillus coli is apparently one of the noxious organisms.

3. "The result of treatment with serum, taken from a case of general paralysis in a condition of remission and injected subcutaneously into an early progressive case, points strongly to the fact that some form of serum therapy is the proper treatment for this as yet incurable disease." He now proposes to use serum from a horse immunized to the bacillus coli.

Dormiol, a hypnotic and sedative, has received attention from A. McGugan,[32] who considers it "equally effective" as chloral and pleasanter though more expensive. Other writers speak favorably of the remedy (see Amer. Year Book M. & S., 1903, 526). The dose is stated at thirty to sixty minims of a 50 per cent. solution.

THE NEUROLOGIC PROSPECT.

The two great problems in intimate relation to biologic progress, "the struggle for existence" and "the survival of the fittest," give us little trouble in a practical sense, since they are solved for us in the vast laboratory of Nature. From the enormous mass of material there worked over, however, there must result, as in most laboratories, a considerable proportion of "by-products," to borrow a chemical term—biologically speaking—of organisms below the standard; again others that are perhaps above it.

In other words, the more or less "unfit" are produced along with the "fittest." This gives rise to a third

problem, which we may term "the utilization of the unfit."

To the various attempts of civilization to solve this problem we owe the existence of medicine, religion, law, ethics and art in general. There arises from its attempted solution such important and perplexing subproblems as:

1. The management of the mentally afflicted and of the physically helpless from various causes.
2. Of the criminal and dangerous classes generally.
3. Of the inebriate and moral invalid.
4. The question of the legal responsibility of various defectives.

Most questions of therapy in general.

In short, the extensive series of problems presented by the necessity for intelligent care of the defective, the delinquent and the depraved. It would be a narrow view from the standpoint of civilization, which would seek only the extermination of these classes, for it is a self-evident truth to the thoughtful, that they are necessary by-products of the laboratory in which Nature works out her most important ends. It remains for us, therefore, to utilize and improve or render them harmless.

The first of these subproblems, the management and treatment of the mentally afflicted and otherwise helpless, so as to obtain the best practical results, is yet in process of solution. Much has been done, but more remains.

A growing tendency to combine the heretofore widely separated subjects of neuropathy and psychiatry is evident from a glance at the world's literature. It is being recognized that their separation has been too radical. By the reception of the acute insane into the general hospitals the best interests of these patients, from a therapeutic and economic standpoint, is often conserved, and at the same time the teaching of psychiatric medicine to the general practitioner is made more effective. It is probable that we have gone too far in the separation of these closely-related subjects and that the complete general hospital of the future must provide for both classes of patients.

In the words of Maudsley: "Mental disorders are neither more nor less than nervous diseases in which the mental symptoms predominate, and their entire separation from other nervous diseases has been a sad hindrance to progress."

Sibbald,[33] in an able article on this subject, says: Wards for mental diseases do not require to be distinguished from other medical wards, and residence in sick wards does not entail the industrial and social injury that as a matter of fact follows residence in an asylum. Such wards have also the advantage over an asylum that a patient who goes there is saved from the mental shock which is often felt on entering an institution largely devoted to the care of the incurably insane. The writer can emphatically indorse this view of the subject from his experience in the wards of the Cincinnati Hospital, where a limited number of acute insane are treated.

The establishment of special or "psychopathic hospitals" for the separate treatment of the acutely insane, is along the same general line of progress and has been vigorously advocated of late years. I need only refer to the able address of my predecessor (vide Dewey[35]) for the details.

Peterson[36] and Brower[37] also contribute important articles on this subject. In the establishment of separate institutions for the epileptic the states of New York, Ohio, Pennsylvania, New Jersey and Massachusetts have already taken an advanced stand, and their example is likely to be followed elsewhere

THE HOSPITAL FOR CHRONIC DISEASE.

In our anxiety to provide proper hospital accommodations for the acutely ill there is some danger, according to Dr. E. W Taylor,[31] that we may overlook the claims of the chronic invalid. At present no provision is made for such except as paupers, in institutions variously characterized as infirmary, poor-house, alms-house, etc.

Dr. Taylor's contention that the interests of these patients and of the public in general would be better subserved by removal of the stigma of pauperism so far as possible is well taken.

A movement toward the solution of the second subproblem on our list has been inaugurated by the establishment of separate hospitals for the criminal insane in New York state, and the subject is now being agitated in Ohio[38] and elsewhere.

As regards the third problem, the care and treatment of the inebriate, it has been solved only so far as the well-to-do are concerned by private institutions, many of great merit and doing excellent work. The work should be extended so as to be available to those of the most limited resources.

In attempting the solution of the problem of the utilization of the unfit the physician has to deal with many who have been launched on the sea of life to make their "struggle for existence" with insufficient vital capital; with others who receive a fair start in this respect, but whose working capital has been impaired by the various stresses of circumstances, which we call "disease" and "accident"; and finally, with the very large number whose dynamic potentiality is sufficient for ordinary needs, if properly directed and conserved, but which fails to meet extraordinary demands or improper use. It is evident that "the strenuous life" is not for either of these classes.

The prophylactic and therapeutic efforts of the physician, therefore, must be largely addressed to the maintenance of nutrition, the regulation of function and the conservation of energy.

TEACHING OF PSYCHOLOGY AND PSYCHIATRY.

As an important adjunct to the better management of the above problems we need chairs of psychology and psycho-pathology in our medical colleges generally. (vide Persching[39]). Many have not even full chairs of neurologic medicine proper. It is largely due to this omission, and the consequent indifference of practitioners to psychiatry as well as psychotherapy, that the various isms, pathies and "cults" flourish as they do.

To successfully solve this problem we must do better than they, i. e., we must add to a sound therapy based on solid anatomic, physiologic and pathologic foundations, the same subtle, but none the less effective, psychotherapy which is the sole weapon of the pretender.

TO SUMMARIZE THE OUTLOOK:

We may look for important aids to neurologic progress, to serum and other antitoxic therapy; to cytodiagnosis and hematologic procedures generally; to organic and electro-chemistry; to prophylactic hygiene and dietetics; to a wise adjustment of function to structure; to special institutional measures and to better facilities for teaching neurology in general, including psychology, psychiatry and psycho-therapy.

The future of neurologic medicine as worked out along these lines will be of vast importance to the welfare of humanity.

"All things come to him who waits," *he who would utilize them must act.*

THE DENTAL NURSE.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON STOMATOLOGY AT THE FIFTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT NEW ORLEANS, MAY 5-8, 1903.

M. L. RHEIN, M.D., D.D.S.

NEW YORK CITY.

In officially opening the meeting of the Section on Stomatology, I desire to tender to the members my high appreciation of the honor conferred in asking me to preside over your deliberations. It has been the aim of our Section to encourage the membership of men who are deeply interested in the scientific advancement of this specialty of medicine. On this account our numerical strength has not been great, and I trust that the members will be prompt in attendance at the opening of all the meetings, so that the magnificent program prepared for us by our worthy secretary will receive the attention and discussion which it merits.

Our propaganda in regard to a better education of the dentist in the principles of general medicine, as well as a better knowledge of dental principles in medical education, is making slow but sure headway. The cause has the hallmark of truth emblazoned on its banners, and is bound to prevail, however prolonged the struggle may be.

It is unnecessary for me to take up your time with a summary of the scientific work of the year. It speaks for itself in our professional literature, with which you are familiar. Our daily occupation as stomatologists includes the treatment of diseases of the oral cavity, primarily with a view to the preservation in a state of health of the teeth, on account of the great value they bear to the health of the general body. The art and handicraft of dentistry has taught us how to cope with dental caries successfully, so that no person in the civilized world at the present day need lose a single tooth from this cause alone.

Many people, however willing they may be to employ our services, are constantly losing teeth in consequence of various pathologic disturbances of the peridental tissues. The symposiums held in past years by this Section on interstitial gingivitis, pyorrhea alveolaris, etc., indicate how well we recognize the increasing number of teeth lost by this means. When this lack of inherent vitality of the tooth's periosteum has reached a certain stage, where not only seven-eighths of the root surfaces are covered by nodular secretions, but retrograde metamorphosis, in its peculiar way, is working towards sepsis and the destruction of cell tissue, we realize that such affected teeth are beyond human intervention. We also know that these very teeth, doomed to be lost as they are when too little vital connection is left, could have been preserved indefinitely if proper hygienic care and treatment had been instituted at the right time and kept up in a systematic way at regular intervals.

Preventive medicine, with its accompanying benefits, has been well understood since the time that Jenner proclaimed the virtues of vaccination. Since then prophylaxis has invaded the domain of nearly every disease and its science and practice is daily increasing and its field of usefulness becoming better known.

Its value in the province of stomatology is well known to the poorest dentist in the land. The cleansing and polishing of every portion of exposed tooth surface, at regular intervals, in such a way as to preserve the tone and health of the contiguous capillary circulation, will indefinitely preserve the life and stability of the human teeth. With a full knowledge of the inestimable value resulting from such systematic treatment, it is painful to admit that, as a rule, the general public get absolutely no benefit from the knowledge of the profession on this subject.

Like many other virtues, prophylactic treatment of the teeth is well understood by all dentists and practiced by only a few stomatologists. It is scarcely necessary for me to attempt to draw a pen picture of what the dentist does under the pretense of cleaning teeth, when requested to perform this service, or to speak of the wilful neglect thereof by the majority, when no especial demand is made by the patient. You have all examined the mouths of such patients, who inform you that for years their mouths have had the constant care of Dr. X., and he has cleaned their teeth every year. You have found secretions of years deposited on the roots. The more posterior and inaccessible the teeth the greater the extent of deposits. You are not surprised at finding such teeth becoming loose, with a surrounding pericementum more or less inflamed, and corresponding loss of soft tissue from superficial necrosis.

They come to us in all stages of tissue loss, from those easily cured to those irretrievably lost. You can not fail to recognize the picture, and neither can you fail to place the responsibility for this wholesale destruction of human teeth on the dentist who has failed to apply the principles of preventive medicine.

Are we to assume, from a study of this sad picture, that our calling is made up of men lacking in character and principle? Most emphatically no; in no specialty will be found men with higher attributes of character, in every sense of the word, than in this of ours.

THE DENTIST'S ASSISTANT.

There are very good reasons why this most important duty to our patients is seriously neglected. The necessity for performing the operations immediately necessary for the repair of existing lesions in tooth structure and adjacent tissue is of paramount importance. They are more than sufficient to take up all the time of the man with an average practice. The difficulty of receiving commensurate pay for the hours of time required in faithfully carrying out the treatment by prophylaxis, brings up the question of expediency. It is true that Dr. Smith of Philadelphia claims to personally give his patients this treatment at regular intervals. If an effort were made to follow out this method in an average practice, there would be time left for nothing else. It certainly is the consensus of professional opinion that the busy practitioner can not give up his valuable time for this tedious, monotonous and irksome labor, however important it may be for the salvation of the human teeth. A small number of us have tried to solve this important problem by employing an assistant practitioner to attend to this department. In the judgment of your chairman, who has tried this method for twelve years, it has failed to satisfactorily solve the problem.

The employment, in a private office, of a graduate to make a specialty of this work is very likely the best remedy we have had at our disposal up to the present time. The greatest objection to the plan is the inability to retain a graduate possessing ordinary ambition and talent a very great length of time in this position. It is impossible to obtain satisfactory results in this treatment if it is necessary every year or two to place a new assistant in this department. The patients object to these changes, and can not fail to contrast the work of the new assistant, who has to be freshly taught the character of the work desired, with the final work of the last assistant, which has become well-nigh faultless from a couple of years of constant practice. In discussing this subject with prominent men, it has been generally conceded that far better results could be obtained if suitable female assistants, not graduates, were specially trained and employed for this work.

In some of the states the examining boards have threatened prosecution for infraction of the dental law if such a course be pursued; consequently, it has not been adopted, much to the loss of the general public.

This brings up the question whether the cleansing and polishing of the teeth, massaging the gums and the application of remedial agents by non-graduate assistants, under specific prescriptions and directions of the attending stomatologists, are infractions of the law.

It might as well be said that the administration of drugs hypodermatically, the introduction of sounds and catheters, lavage and enemata, the dressing of wounds and numerous other services performed under medical direction by trained nurses are all infractions of the medical law. Take away the trained nurses from the physician and surgeon and it would be apparent at a glance how it would interfere with the number of his cases, to say nothing of the inferiority of the resulting attention which is such an important adjunct whenever the nurse is in attendance.

THE DENTAL NURSE.

If this correctly describes existing conditions, it follows, as a natural conclusion, that the problem of how to systematically carry out the prescriptions of dental prophylaxis would be easily solved by the introduction of the trained dental nurse.

In the State of New York, during the present session of the legislature, a law is being passed, placing the trained nurse under the jurisdiction of the State Board of Regents, which necessitates that they should possess the proper qualifications in education and practice. In view of the high esteem held for the work of the trained nurse, it appears remarkable that the sphere of her usefulness has not long since been extended to our own specialty.

It would be an easy matter to add to the training schools for nurses a department of dental nurses. Applicants for admission to such a course should be required to pass a satisfactory preliminary examination. Outside of the general didactic instruction which they would receive, they should obtain additional instruction in regard to the oral cavity, etc., from a stomatologic member of the school's faculty. They would also receive their manual training under the same supervision, and in the hospital material they would find ample opportunity for perfecting their working technic.

It is difficult to estimate in advance how much benefit would accrue to a large percentage of hospital cases if their mouths could be properly cleansed and rendered sterile.

Would it be claiming too much to say that there are serious conditions where such treatment properly administered might prove the turning point toward recovery or, in organic diseases, toward a material improvement in the general condition? Perhaps their greatest sphere of usefulness would be to place the mouths of patients in a sterile condition preliminary to undergoing surgical operations. When we consider all the devices used in the modern operating room, all devoted to obtaining ideal aseptic conditions; when we consider the patient anesthetized in an atmosphere barren of pus germs, with the single exception that too frequently the patient's mouth is redolent with putrescent filth, washed with secretions of pus; when we consider such conditions, with a celebrated surgeon about to enter into the digestive tract, can we longer question the value of the preliminary treatment by the dental nurse in such a case? Then there is the infirmary practice connected with all the large hospitals. Here is a field for the doing of the greatest good to this vast class of unfortunates. The cleansing of the mouths of properly selected patients in the dispensaries, combined with the proper education for preserving oral hygienic conditions, would be of greater value in the uplifting of the masses than any other means at present employed.

Having graduated from the training school, it would be in keeping with our other laws to compel the nurses to pass a state board examination. The passing successfully of such an examination would then entitle them to be registered as trained dental nurses. Being so registered, they would be able to practice their profession in private life. By that is not meant the fact that they would be licensed to go around indiscriminately, cleansing the mouths of the people.

Their license to practice dental nursing should mean that they are permitted to cleanse, polish and medicate the dental territory only under the prescription of the patient's attending stomatologist.

As chairman of your Section, I ask your approval for this means of placing within reach of the human race, the boon of prophylaxis in stomatology. There are three good reasons why it should receive your endorsement: First, it will tend materially toward the public good. Second, it will open to womankind a new vocation second to none in desirability. Third, it will materially aid the stomatologist in the quality of his results.

38 East 61st Street.

DISCUSSION.

Dr. M. H. Fletcher, Cincinnati—I fully agree with the ideas advanced, and it seems to me there should be channels through which we could bring the matter prominently before the public, but we all know how long it takes the public to receive a new fact. Darwin's theories have only begun to be accepted. I believe if it were possible in some way to advertise the simplicity of this plan the matter would advance in general favor very rapidly. All dentists know that such treatment is most desirable. To begin at home, those who teach should impress it more fully on their students. We should teach all our patients that the simple fact of cleanliness prevents disease as much or more than anything else. To impress this fact on those with whom we are in daily contact, I think, should be our conscientious duty. It would seem becoming in us as a company of progressive men to give our endeavors to the accomplishment of some plan whereby the suggestions in the address can be carried out.

Dr. Geo. J. Friedrichs, New Orleans—I do not take much stock in the continual teaching and preaching of cleanliness as a prophylactic; the mere knowledge that cleanliness is a prophylactic does not always result in benefiting those who most faithfully carry out the teaching. This rule applies to mankind in general. A physician is certainly well posted in regard to the effects and consequences of the abuse of morphin, alcohol, etc., yet in spite of his knowledge becomes their slave.

Dr. M. L. Rhein, New York—In setting forth this proposition it has been my object not to enter into any question of etiology or methods of treatment, or anything of that kind, but to consider simply the advisability of adding to the dental laws in the various states a clause, not necessarily permitting the employment of dental nurses, but defining their limitations, making it apparent that they are legally entitled to be of use. I am certain that as a physician if I desired to employ a nurse for this purpose I have the same right to that use as I have in any other capacity as a physician, and I am sure I could carry my point legally; but it is my desire to have their sphere well defined so that there would be no objection to their use by the general dentist. I do not care to enter into the question of how difficult it is to bring a new plan before the public, but in my own mind I am certain that if my plan meets with general approval the next step will be easily accomplished, that is, the addition of a training school for dental nurses to the regular training school for nurses. I trust that the gentlemen, in order to facilitate the other business, will give the Section the benefit of their thought on simply this particular point.

Dr. George F. Eames, Boston—I have in my practice carried out many of the principles which Dr. Rhein has enunciated here, and have trained assistants to supplement me, rather than to take entire charge of what we may call prophylaxis. When I begin a prophylactic treatment of the mouth my assistant usually sees what I do. I take opportunity then to explain what is to be finished or I direct such an assistant to do such and such things. When a graduate receives his diploma from a dental college or from any institution, it grants him certain privileges, but it is understood that with these privileges within the law there are also certain restrictions. It is so with the appointment of graduate nurses or dental nurses. They do have the privilege of doing certain things within the mouth under the direction of the stomatologist, but there are restrictions to this as well as to other privileges. It seems to me we can not but endorse the plan that has been suggested by our chairman.

Dr. Thomas L. Gilmer, Chicago—I thoroughly agree that it is necessary to have a better way of accomplishing the work spoken of than by the methods now prevailing. How we can bring this about I do not know. It would be better, it seems to me, to have regularly educated specialists for the work. The treatment of diseases of the mouth offers a good field for specialized workers. It does not seem to me that we could safely trust the treatment, for instance, of the so-called pyorrhea alveolaris, except the merest first cleaning of the teeth or some subsequent medication, to any one not thoroughly skilled in the work. I consider the treatment of this disease one of the most difficult things we have to perform, that is, the thorough removal of the serum deposits and the surgical treatment of the alveolus. As to the training of nurses in the hospital for the care of the mouths of their patients, I am in accord; and in my connection with hospital work and the teaching of nurses I give positive and detailed instruction to the nurses in the care of the mouth, and especially in the preparation of the mouth previous to surgical operations. We should continue the education of the people by personal advice in the care of the mouth and teeth. I believe I save more teeth and do far more good in the prevention of disease of the mouth by constant insistence and admonition on the care of the mouth by the patient himself than by all other means.

Dr. George J. Friedrichs, New Orleans—My remarks were not to find fault, but to commend, for "cleanliness is next to Godliness." Since cleanliness is helpful, but is not an absolute prophylactic of tooth structure, we must also look on the other side.

Mr. T. E. Constant, Scarborough, England—None of us have any doubt at all that the public would be greatly benefited by such a scheme. Our laws in England are such that the education of such a body of semitrained people might act injuriously. Whether this would be so in this country I am not in a position to say, but that is the aspect of the question that we would have to consider. On the broad question as to whether the suggestion is a good one for the public generally I think there could be but one answer, that which has been given by the other speakers.

Dr. W. E. Walker, New Orleans— I do not see any harm that could come from the plan and I can see infinite good to come from it. When in general practice a very large portion of my time was spent in doing the very work that the paper suggests, having great assistance in the work by lady helpers. While I would certainly agree with Dr. Gilmer that the treatment of Riggs' disease from the surgical standpoint would be rather unwisely placed in the hands of such semitrained assistants, at the same time they could be of great assistance if used somewhat as Dr. Eames says, to supplement the work of the dentist; and the paper does not carry with it anything more than a proposition to supplement with the addition of legalizing their practice. As the Doctor said, he has a right to employ trained nurses to help in this work, whether they come from a training school or have been trained individually. But, the idea seems to be to make it beyond the possibility of criticism should they be employed by a dentist who is not a physician, that he may freely employ these trained assistants in his office and not run any risk of criticism or legal complication. It would certainly seem to me much better than, as the Doctor says, employing undergraduates that you can not hope to keep with you more than a year. I certainly can not see any objection to it, and I hope the Section will endorse the ideas.

Dr. H. E. Belden, New Orleans—I think we should have dental assistants to carry out our wishes in cleaning the teeth. The cleansing is an irksome task and demands a great deal of time and attention. The lines for a livelihood are

closely drawn and we have to devote ourselves to the more scientific and lucrative tasks in our profession, and if we can put off those duties which can be performed by trained assistants I think it becomes us to do so. We help our patients by giving them more treatment (by our trained assistants carried out under our supervision) at the same expense to them and greater profit to ourselves, as we can give more attention to those things requiring greater skill.

DR. C. V. VIGNES, New Orleans—I think the idea of having such trained assistants is a very good one. From a legal standpoint, I don't know what condition exists in England, but I know that here anybody can practice almost what he wants. It is suggested that these special trained nurses be women because the young man or graduate at the end of a few months would go into general practice. I believe that the trained nurse would do about the same thing. She would go into general housekeeping. I don't know how it obtains in other parts of the country, but down here trained nurses are pretty liable to get married. The vocation appears to be a stepping stone to matrimony. I believe the field is a large one for young men, and that it would assist a great many to earn an honest living and keep them in the straight path; that is, they would practice in an ethical manner if they had the right start. I think it is an opening, not so much for the trained nurse as for the benefit of the young dentist who has a very hard road to travel.

DR. EUGENE S. TALBOT, Chicago—I have no fear as to the future education of the dentist. The experimental stage is passed. Dental education commenced to shape itself when universities established dental departments. Although for fifteen or twenty years after that time there seemed to be a chaotic condition, yet the past five years has worked a wonderful change in the department of dentistry. The adoption of a four years' course is the culmination of the educational problem from a dental standpoint. The university will place this department of medical science on an equal footing with other specialties of medicine. The Section on Stomatology of this Association has played a prominent part in shaping dental education in America, and I for one am perfectly willing to let the universities work out the problem.

Credit should be given the late Dr. A. C. Hart, San Francisco, for suggesting the cleansing and polishing of the surfaces of the crowns of the teeth. Scientifically he did more in the study of this method than any individual. His death was a result of his enthusiasm along this line of investigation.

I agree with Dr. Rhein in relation to specially prepared women for the care and cleansing of the teeth, as first suggested by Dr. Wright, Cincinnati. That such women should be connected with hospitals to care for the mouths of the sick is certainly very important. How physicians can expect to treat their patients sucessfully with uncleanly mouths is a problem. It would seem to me that this paper should not only be published in THE JOURNAL of the American Medical Association, but later in all medical journals in this country and in Europe, and that reprints should be sent to all the hospitals. Every physician should read it. The dentist should insist on his patients coming to his office every three months and have the teeth cleansed. When the patients understand that by so doing they are saving dollars in fillings, etc., they will readily acquire this habit. If all dentists would do this the public would be educated soon to this method.

DR. M. L. RHEIN, New York—In my practice the plan of the return of the patient, as mentioned by Dr. Talbott, is pretty well in effect. Every one of my patients is sent for at regular intervals. The value of this method as a preventive of caries was not touched on. The removal of the racemose leptothrix, which is so baneful in its effects in early life, is of the utmost importance as pertaining to this subject.

In regard to Dr. Gilmer's remarks, it is far from my purpose to permit a trained dental nurse (if I may use the term) to perform what he and I, and I believe all dentists, consider one of the most serious and difficult surgical operations. That they should not be permitted to surgically clean alveolar sockets in peridental diseases, or do any of the ordinary forms of dental work is the main object I had in introducing this matter and in asking for your approval of the suggestion to legalize the position of a dental nurse so as to legally establish the limits of her sphere of usefulness. Personally I would prefer that these assistants be women, the reason for which I will not take the time to explain. In my opinion they might be permitted to remove deposits in normal mouths, but in distinctively pyorrheal and interstitial gingivitis their duty would come only after the surgical work had been completed by the surgeon. They would follow his direction in thoroughly polishing the tooth structures and in medicating the tissues. In conjunction with this comes up the point raised by Mr. Constant. His objection to its usefulness is based on a condition of legislation which does not exist in the United States. I understand that in England the passage of such a law might give improperly trained persons an insight in dental practice and thus enable them to take an improper opportunity to work their way before the public as dentists without being interfered with by the law. In the United States, in most of our states, at the present day, the laws are rigidly enforced. This is especially true in the eastern part of the United States, and here it would be impossible for infractions of the dental law to go unchallenged. I would also say, in reply to Dr. Gilmer, that it is a great pleasure to me to know that there is one hospital in the United States where the mouth is properly prepared preliminary to any surgical operation. I know of no such condition in the city of New York. In that respect we are rather behind the west. Outside of that one hospital I think the general surgeons in Chicago or of the northern cities do exactly what the general surgeons do in the east: when they open the peritoneum, when they have an operation for appendicitis, or a laparotomy, the condition of the patient's mouth is not considered. That has been my experience in the east, and I have seen some such conditions in the west. I do not for an instant suppose that any of us who do surgical work would permit any patient of ours to go on the operating table in such condition. I refer to those medical men who are absolutely devoid of the ordinary rudiments of knowledge as to the oral conditions and the septic influences that may proceed from the oral cavity.

SUNSHINE AND FRESH AIR VS. THE FINSEN ULTRA-VIOLET RAYS AND THE ROENTGEN RAYS IN TUBERCULOSIS OF THE JOINTS AND BONES.*

DE FOREST WILLARD, M.D.

Clinical Professor of Orthopedic Surgery, University of Pennsylvania; Surgeon Presbyterian Hospital.

PHILADELPHIA.

The increasing use of the Finsen light and of the *x*-rays in the treatment of cancerous lesions of the skin and deeper tissues, and especially their use in lupus and other tubercular skin affections, naturally arouses the question of the utility of these rays in the cure of tuberculosis of the joints and bones. The results thus far obtained are certainly sufficient as regards tubercular lupus to warrant the continuance of our efforts in this direction, but the opportunities for noting the effect on deeper tissues in tubercular joints have not yet been sufficient to warrant definite conclusions. A large number of cases will be required to decide the question of benefit, since from the nature of the disease speedy conclusions will be unjustifiable. The course pursued by the tubercular process in joints is always slow, and there are such great dif-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, De Forest Willard and J. E. Moore.

ferences in the rapidity of progress that the surgeon is very likely to draw wrong conclusions from the results of any method of treatment instituted.

The inhibitory action of the actinic light ray and of the *x*-ray on the growth of tubercular bacilli in the laboratory is undoubtedly positive, and such experimentation is an essential part of our progress in accurate knowledge. Combined with these experiments, however, must be careful clinical observation and an accurate recording of facts as they present themselves. I am free to confess at present writing that no definite conclusions can be formulated; only that progress, though slow, is hopeful. At the present time we are erecting at the University Hospital a complete plant for the thorough testing of the therapeutic effect of these light rays, and also of the *x*-rays, and I trust that at the end of five years certain positive data will be secured.

Any method or form of treatment that will tend to retard or inhibit the growth of these bacilli is helpful in the long fight with tuberculosis, and the part of the surgeon must be twofold: First (and I purposely put this proposition first), the fortification of the individual for the conflict; second, the destruction of the enemy.

The secret of success in the battle with tuberculosis of the bones and joints rests overwhelmingly on the resistive power of the individual. While, therefore, the Finsen light and the *x*-ray may have their effect in retarding or inhibiting the growth of the bacilli in a local area, it should be remembered that even the total destruction of this small company means but the temporary crippling of the invading army, and that real safety lies entirely in the permanent upbuilding and strengthening of the resistive powers.

The tubercle bacilli are vegetable parasites subject to the fundamental laws of organic life. Their growth is favored by a lack of resistance of tissues and by a fertile soil. This lack of resistance may be due to traumatism of moderate, rather than of severe, degree, or to temporary constitutional causes, or it may be the result of an inherent and hereditary cell weakness. When special soil and special environment are provided, these bacilli will run a speedy and definite course. That their course can be retarded or totally inhibited is definitely proven both in laboratory and clinical experience. Their growth is facilitated by darkness, dampness, moderate hyperemia and all depressing physical and mental influences. They are resisted by light and air and food, and thorough oxygenation of the tissues, by environment, soil and phagocytic defense. The absence of any of these favorable conditions means growth; their presence, destruction of the foe.

The most powerful agents in our possession for the inhibition and destruction of these micro-organisms are sunlight and fresh air and abundant nourishment. The sun's rays are undoubtedly more helpful than any artificial rays, just as natural waters compounded by the chemistry of the Ruler of the universe differ very decidedly from the waters artificially compounded by the chemistry of man.

While experimentally the strongest sunlight in summer takes more than an hour to kill bacteria, yet the ultimate influence is undoubtedly more beneficial than artificial contrivances. The large proportion of hours of sunshine in Colorado undoubtedly has much to do with the reputation of that region for the cure of tuberculosis. The beneficial effect of the sun bath was well known to the ancient Greeks and Romans, and we have been too tardy in again bringing into service measures which they learned from practical experience, and which we in our blindness have overlooked. As surgeons, we can with benefit learn a lesson to-day from the washerwoman and the farmer.

In my own hospital wards I have always considered the sun porch as the most important of all the means of cure. Every tubercular joint case confined to bed, either with horizontal extension or with fixation or traction of joint, spends the entire day at all seasons lying directly in the sunshine, his eyes and head being protected by a green shade attached to the head of the bed. The effect on health, appetite and cell resistance is simply marvelous. When able to walk about, patients are encouraged to play in the sunshine, not in the shade. I have not infrequently sent out into the sunlight and fresh air apparently hopeless cases of joint disease with lardaceous organs, and have had them return with sinuses healed, waxy changes arrested and health restored. Of course, it is necessary that surrounding conditions, even in the country, shall be healthful, since many farm houses are unsanitary in the extreme.

In the treatment of tuberculosis of the joints not only are mechanical and operative measures necessary, but all the accessory conditions of health are essential: a superabundance of easily digested and nutritious food, and clothing adapted to the surrounding conditions, in addition to the sunshine and air. There are few individuals who have not observed the influence of darkness and poverty and vice on the general health, and yet few physicians realize the importance of securing the brighter and better conditions. The time is near at hand when sanatoria for the treatment of tuberculosis of the hard parts, as well as those of the soft tissues, will be established. Outdoor life in tents, either in the pine forests or in the hospital grounds, promises a simple practical application of the principles enumerated. Cheeks will grow more rosy, flesh will increase, energy will improve, and resistive power will speedily be such as to control and overcome the tubercle bacilli.

McKenzie and Galloway[1] have also adopted this most excellent principle of treating cases of tuberculosis of joints in the open air by having them live in tents, thus giving patients all the advantages of sunshine and fresh air that are now in vogue in the lung tuberculosis sanatoria. The appetite is greatly improved under such conditions; more food is taken, and it is better digested.

Dr. Flick's regulations at the White Haven sanatorium for consumptives are just as applicable to joint tuberculosis as to phthisis cases: patients to live in tents and to spend their life absolutely out of doors, air to circulate freely through the sleeping apartments, ample bed covering to be supplied. Each patient to take at least three quarts of milk and six eggs a day; more if possible. In addition, a good dinner in the middle of the day, and a light breakfast and supper. Dinner of roast beef, vegetables and dessert. The gain or loss in weight are the best indications for adaptation of treatment and food.

Poncet, of Lyons, and Perdu and Blanc[2] have also applied the method practically by exposing joints covered with iodoform gauze to the direct action of the sun for hours in the day. As the case recorded by them, however, had had a previous excision of the knee, the report only shows that the sun's rays acted helpfully in the cure.

Eve[3] applied the light and heat of ordinary electric light bulbs (96 candle power) to a number of cases of arthritis with benefit. Mobility increased and pain was almost entirely relieved. The limb was placed under a canopy made of blankets thrown over a cradle, and the

heat raised to 250 F. The beneficial effects of the heat seem to have been increased by the bright light.

Kime[4] uses direct sunlight, concentrating it through an adjustable photographic ray filter, a plano-convex lens of 18 inches focal length and 6 inches in diameter. Behind it, ¾ of an inch distant, is placed a plain plate glass. Between the lens and the plate glass is a space for the blue copper alcoholic solution, which cools the sun's rays and absorbs all but the blue or actinic rays, which are rich in their chemical and germicidal powers. Although such a light focussed to a small point is hot, yet it can be regulated so as only to produce hyperemia, new vigor, new cell action and repair.

Heliotherapy or actino-therapy would probably be the best designation for this method of application of the concentrated sun's rays to the cure of disease; electro-phototherapy for the condensation and application of electrical rays to the same purpose.

Within my recollection, Butler in the 60's, successfully employed sunlight for the treatment of epithelioma of the skin, using for the purpose an ordinary biconvex lens.

Finsen at Copenhagen, Rikli, Koch, Strauss, Arloing and others, deserve great credit for their experimental and practical application of the bactericidal action of the sun's rays.

Finsen has shown by his experiments that the blue, actinic or chemical rays, which include the violet and ultra-violet rays, are the only ones that have an especial influence upon animal life and are bactericidal. The red, green and yellow heat rays have no effect upon the micro-organisms. It is the actinic rays which produce sunburn, not by burning the skin, but by slight irritation which produces the pigment deposit. Finsen also experimented with the effect of rays of the sun in smallpox cases, and found that if the patient was kept under red glass and red curtains, etc., that there was no scarring. The concentrated sun's rays have been proven by experiment to be capable of destroying bacilli in a few seconds, instead of hours, and it is also claimed that a concentrated electric light in which the ultra-violet rays are in abundance has a greater bactericidal power than even the sun's rays. These ultra-violet rays in the electric light are in shorter wave lengths, while in sunlight they are of longer wave lengths; the shorter ones have already been absorbed in the atmosphere.

The actinic rays penetrate much deeper into the tissues when the latter are rendered bloodless by pressure or by ice. The passing of the ultra-violet rays through ice renders them more destructive to the tubercle bacilli from the fact that the chilling of the skin by the ice renders it more anemic, and thus gives the rays a better opportunity to act upon the bacilli. Ice is transparent to the violet and ultra-violet, but is opaque to the red and ultra-red rays. Pigmented skins and cicatricial tissue interfere with the penetration of light rays, as does also great vascularity. The skin and intermediate parts should be protected when the *x*-rays are used, but do not need protection, save from the heat, from the Finsen light. In order to retain all the ultra-violet rays (which are the most efficacious) blue sulphate of copper was first used, as blue excludes the red rays, but now only ordinary cold running water is employed between the lenses to arrest the red rays and cool them. Finsen also used a lens of rock crystal in place of glass, in order to allow the ultra-violet rays to pass through more easily. The lamps used were from 25 to 75 amperes, since above that strength it was found difficult to cool the rays sufficiently by the use of water. Finsen's large lamps have 35,000 candle power.

In the lamps made in London by Marshall and Woods and Leslie Miller, an interrupted current is used of about 12 volts, and the sitting is prolonged from five to twenty minutes. With some of the new lamps an area of the size of a dollar can be treated at one exposure. In the sunlight baths, Finsen has his patients walk about naked. Finsen's electric bath consists of gigantic arc lights, 100 amperes, suspended six feet from the floor. Patients lie naked on couches. He uses the voltaic, instead of the incandescent, as the former contains more chemical rays. His theory is that the chemical light bath differs materially from the incandescent light baths.

If the *x*-ray can modify local tuberculosis (Muhsam, Fiorantine and others) the Finsen rays are much more likely to produce a beneficial effect.

The lamp now used in the Broca Hospital, Paris, is smaller than Finsen's and more easily handled. The carbon is made with a core of cast-iron, thereby emitting, it is claimed, three times greater amount of ultra-violet rays. The exposures only last twenty minutes, instead of seventy-five, and 30 amperes are used instead of 75 or 80. Anemia of the tissues by pressure is also not considered essential, and the application is made once in two days.

Kjeldsen's lamp is less expensive than Finsen's, and does not require specially trained nurses for its application. Lamps of 5 amperes are employed, and instead of carbon, iron electrodes are used, which are very rich in chemical, and very poor in heat, rays. It is claimed that a lamp of 5 amperes gives the same result in three minutes that is given in an hour by the use of 80 amperes with the old apparatus, the cost being about one-tenth, and the assistants required being few. It is also claimed that tubercular bacilli, gonococci and streptococci, and bacteria coli communis were inhibited by the light in five seconds, and that anthrax was killed in thirty seconds.[5]

Widmark, of Stockholm, used but a 1,200 candle power electric light, passing the rays through water to absorb the heat rays, then by carrying the rays through a plate of glass, he excluded the ultra-violet rays and reported that under the influence of all the rays except the ultra-violet, the skin was unaffected; under the influence of all except the heat rays, the characteristic inflammatory symptoms developed. It seems probable, therefore, that the ultra-violet rays produce the known effects of light upon the skin.[6]

Erythema solare may be avoided by care and by the not too rapid use of the rays.

If the current is too strong the skin swells and redness and blisters may appear, but sloughing does not occur. Pyrogallic ointment has been used in lupus to make the skin more penetrable to the rays, and may be also useful in joint disease.

The disadvantages of the Finsen method, which will undoubtedly be lessened when the practical mind of the American applies itself thoroughly to this subject are: first, the limited area of the body which can be exposed to the ray of a single lens; second, the length of time required, and third, the large staff of special nurses that must be engaged. An area of only one and a half centimeters can be treated in an hour.

The cost of the running of the Finsen light is a serious one. A recent estimate makes the expense of a four-light lamp for a year to be $3,000.

As regards the risks, the reaction caused by the ultra-violet rays is much less severe than that following the use of the *x*-rays; the heat rays being interrupted by a stream of cold water, there is, of course, less danger of

burning of the tissues, and the tanning or sun-burning of the skin renders increasing strength possible.

King has advanced the theory that the parasite of malaria scarcely ever develops except in darkness, and that it may be the red color of the blood that favors its life, while the violet rays interfere with its evolution. His theory of the action of quinin in the cure of malaria is based upon the fluorescent properties of the drug, which act as a destroyer of the malarial parasite, and that esculin and fracsin give the blue rays. Iodin, which is not fluorescent, unites with the starchy substances in the system, forming an intense violet blue. Methyl blue, which has been introduced for chronic malaria, may also act in the blood by producing rays which are injurious to the growth of the malarial parasite. The painting of the skin with methyl blue is said to enhance the efficacy of the rays.

General Pleasanton's[7] "blue glass theory," which was lauded thirty years ago, undoubtedly had some merit. He built his sun rooms with every eighth pane of blue.

The theory advanced by Bean[8] seems reasonable that a restorative change may be effected in a pathologic cell by which instead of being destroyed, its character may be so altered that it becomes again a normal cell. Such a change may be occasioned by exposure to light, by alteration of temperature, or by some vito-chemical alteration or molecular vibration at present unknown to us. Each individual difference in rapidity of vibration of the light waves evidently has its special effect on cells. If such be the case it is not necessary that the rays should have positive bactericidal influence, but only that they possess an alterative effect.

The photo-chemical properties of sunlight and of the electric Finsen light require much further investigation, both as to their physical and their therapeutic properties.

The observation was made long ago that the course of tuberculosis differs in brunette and blonde children. Recent observations made upon calves used in the manufacture of animal vaccine, show that the pustules do not develop as well in animals with a dark hide, but that the light-skinned ones are preferable.

Light rays cause contraction in living protoplasm,[9] but Hammer does not believe in the direct action of light on the blood corpuscles. He supposes that certain nervous elements of the skin, in connection with the pigment cells, are put in motion by the ultra-violet rays, and that this motion leads secondarily to hyperemia, inflammation and pigmentation. His experiments on tadpoles, salamander eggs, earthworms, etc., endeavoring to explain the phenomena and to study the relationship between motility of cells and monochromatic light are interesting in showing that light provokes movements in the fetus, and that this faculty must be attributed to the violet rays. White light causes sensibly less action. It is the chemical ray undoubtedly which is the special agent in influencing cell action. Electric light baths and incandescent lamps contain very few chemical rays, not, in fact, as many as ordinary daylight. They can not, therefore, possess the influence of sunlight. These electric light baths probably affect the cells through their heat rays, while a chemical light bath acts differently.

The Roentgen or *x*-rays have been used by myself, by Murphy and a number of other surgeons in the hope of influencing the tubercular process in joints and bones. As remarked in the earlier portion of this paper, it is too soon to determine results, for the reasons there set forth.

The *x*-rays have been proven to have an inhibitory influence not only on the tubercle bacilli, but also on the cholera spirillum, the prodigiosus and the colon bacillus. In the laboratory, after twenty to thirty minutes' continued exposure to the rays, many of the bacteria are killed, and multiplication ceases in nearly all. Some of the micro-organisms, however, survive. Experiments on animals do not seem to warrant the conclusions that the same action can be expected when these pathologic cells are surrounded by living tissues. Animals inoculated and exposed to the *x*-ray have died sooner than similarly inoculated animals not thus exposed.[10]

Various theories have been advanced as to the method by which the *x*-ray energy is exerted on the cells; each theory has been succeeded by another as equally plausible, but all lack positive demonstration.[11]

The bactericidal power is apparently not due either to the heat, the fluorescent light, electricity or ozone.

In our present state of experimentation various therapeutic methods will be employed. One of these has been the alternation of the Finsen with the *x*-ray; Finsen one hour; *x*-ray, five to eight minutes. The Finsen light has less penetrating power than the *x*-ray, but the combination of the *x*-ray to destroy the germs and the Finsen to act as a curative agent seems to be most advisable. The hard *x*-ray tubes have apparently greater penetrating power than the soft. Tanning of the skin is best done by the slow process. The skin and intermediate parts should be protected when the *x*-rays are used, but do not need protection from the Finsen light, save by cooling.

The amount of irritation produced by the *x*-ray on a part depends on various conditions; the distance from the tube, the time of exposure, the hardness or softness of the tube, the cutaneous idiosyncrasy of the patient, the length of exposure and the personal equation of the experience of the operator. Undoubtedly, however, the nearer the tube and the longer the exposure, the greater will be the danger of burning.

The experiments with *x*-ray on cancerous growths, especially of the skin, and even of the deeper tissues, leads to hope that the life process of tubercular cells may be altered, and that destructive changes may be retarded, if not altogether inhibited.

The superficial effect of either the Finsen or the *x*-ray on lupus can not be taken as a guide to their effect on deeper tissues in the joints and bones, yet we may reasonably hope that if the former can be influenced, human ingenuity will in time discover a method for the alteration of deeper tissues. In this connection it is interesting to note the recent achievements of Goodspeed that the wave or ray emanations from the human body are sufficient to impress a photographic plate. Very remarkable also are the continuous forces emitted from that new metal, radium. With the advancement of science and of medical knowledge, tuberculosis must and will be conquered.

The application both of the *x*-ray and of the Finsen light is rapidly becoming wider in its scope, but they should be used not as a substitute for mechanical and operative measures, but to supplement them, and to improve or cure the inoperable cases.

CONCLUSIONS.

1. Sunlight, fresh air and good food, together with fixation and protection of the affected joint, are the most important agents in the contest with tubercular infection.

2. Direct exposure to the rays of the sun is essential, and all hospitals should be provided with solaria or sun porches and roof gardens.

3. Patients lying in bed should have the diseased joints exposed to the direct rays of the sun, their heads and eyes being protected by green glasses or shades. The joints may be covered with blue, so as to secure easiest passage of the ultra-violet actinic rays, and local medications rich in iodin may be also employed as desired.

4. Tent life on the hospital grounds, or better, in the open pine forest, can be successfully employed through both summer and winter.

5. Sanatoria should be established for tuberculosis of the hard tissues, as well as of the soft.

6. The concentration of the sun's rays by lenses, as suggested by Butler, Finsen and others, is of positive benefit in bactericidal influence. As final curative agents, however, the direct sun's rays are most effective. Electrical rays can be used when sunlight is lacking.

7. The Roentgen rays in the laboratory have an inhibitory power on the tubercle bacilli, and may prove useful in restraining the growth of these micro-organisms in living tissues.

8. The actinic rays and the *x*-rays are both apparently helpful in the fight with tuberculosis, but several years will be required to determine accurately their effect. They should be employed not to supercede, but to antedate and to supplement operative procedures, to assist the mechanical protection of the joint, and to increase the general therapeutic measures employed.

A STUDY OF THE HISTOLOGIC CHANGES IN EPITHELIOMA UNDER THE *X*-RAY.

A PRELIMINARY REPORT.*

J. CLARK STEWART, M.D.
Professor of Principles of Surgery, Medical Department University of Minnesota.
MINNEAPOLIS.

The striking and unforeseen curative effects of the Roentgen ray on epitheliomata make it probable that a careful study of the histologic changes occurring in these tumors while under treatment must prove both interesting and instructive.

Medical literature is rather barren in studies of this sort, most opinions put forth being founded on insufficience or absence of observed facts. Note the opinion solemnly set forth in a journal devoted to the exploitation of *x*-ray work: "The beneficial influence which the agent (*x*-ray) undeniably exercises on superficial cancer is due to *x*-ray vibrations acting on the cell elements of the growth, which elements are too weak and lacking in vitality to reach maturity and become the specialized tissue for which they were destined of themselves, in such a way as to give them new vitality, and hence ability to reach maturity and their normal ultimate structure."

That is, the *x*-ray is a sort of reformatory treatment by which the erring cancer cells are spanked and brought to a realizing sense of their vagrant ways, become reformed and proceed to grow into normal adult tissue; a very beautiful effort of the imagination, but needing a substratum of facts.

Many equally remarkable explanations of the *x*-ray effect could be quoted, but this one will suffice.

Dr. A. G. Ellis has made an important contribution to this subject from a strictly scientific standpoint in the *American Journal of Medical Sciences*, January, 1903. He studied four cases, two of which were epithelioma, which had been subjected to varying amounts of exposure to *x*-rays, and has determined some interesting facts. As he gives the literature at length, it will not be necessary to quote authorities.

His conclusions are that the study of these cases shows: 1. Necrosis of cells and trabeculæ of varying

Fig. 1.—Photograph of Case 1 before treatment.

degree. In Case 1 (a cancer of the breast) there is marked fatty degeneration. 2. Increase of elastic tissue. 3. Fewer areas of lymphocytic infiltration in one case after exposure, about equal numbers in others. 4. A tendency to occlusion of vessels by deposits on their inner surfaces. 5. Practically entire absence of infiltration by polymorphonuclear leucocytes. He says: "The unsatisfactory clinical results, as well as the slight microscopic changes in Case 3 (epithelioma) can probably be safely attributed to the presence of the exceedingly numerous keratinized areas or 'pearls.'"

The results of the present study are quite at variance with the above in many respects, as will be seen later. The larger part of the material studied was obtained from one case, which came under observation Dec. 10, 1902, and the research work was begun December 18, some time before the publication of Dr. Ellis' paper.

CASE 1.—A. B., Norwegian, aged 52, single, gave the following history: Eighteen months ago he cut the back of his right hand with a beer bottle, and the cut became infected and healed slowly with a dense raised scar. Soon after an elevated wart-like growth appeared in the scar, which was repeatedly cauterized with pure carbolic acid without much effect. His general health has been good. There is no cancer in his ancestry

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

or environment. An examination shows a fungus ulcer about three inches in diameter on the back of the right wrist. It is raised above the skin more than one-half an inch, the elevation being greatest at radial edge. The extensor tendons of the fingers move freely, but just at their radial side the growth

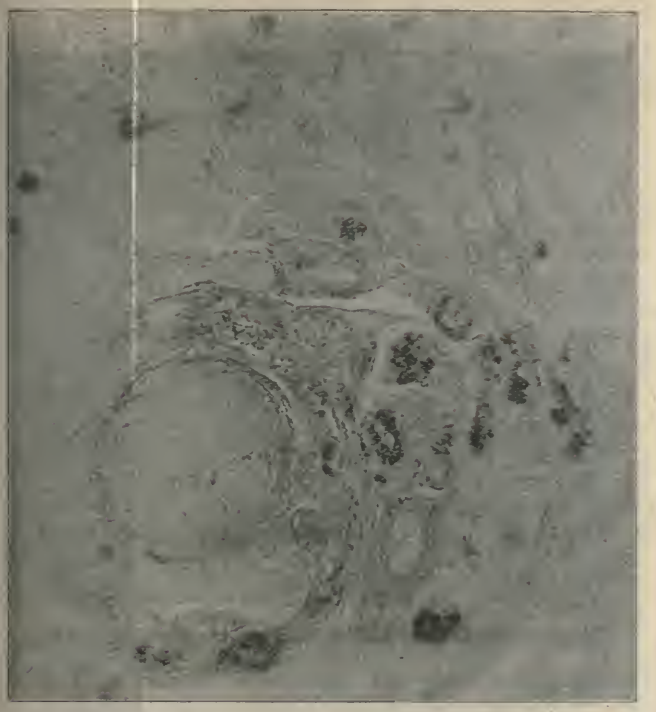

Fig. 2.—Fatty degeneration in epithelial pearl. Hermann fixative 500 diameter.

has deep attachments. There is no enlargement of the axillary lymph nodes. In view of the impossibility of excision it was decided to subject the growth to *x*-ray treatment, as it seemed the only chance of saving the hand.

On December 10, 11 and 12 he was given twelve minutes' exposure to a one-inch tube at five inches. On

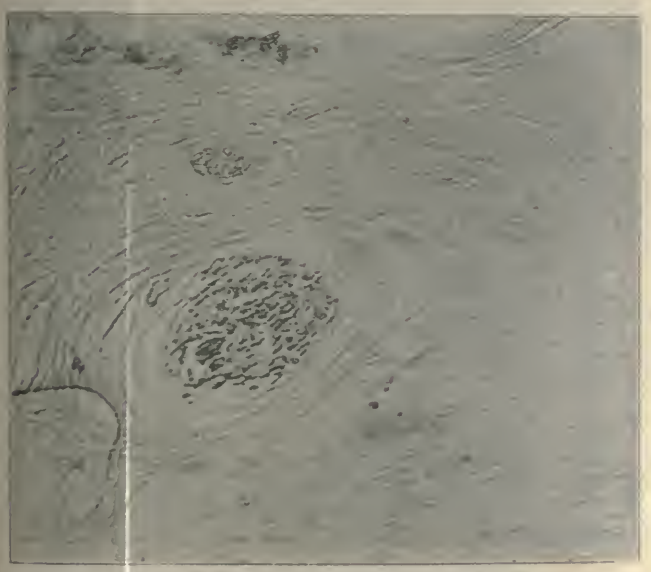

Fig. 3.—New blood vessel containing red blood cells in center of epithelial pearl.

December 16 and 17 he was given fifteen minutes at five inches. On December 18 the first block was excised, being cut from the non-sensitive surface of the ulcer, half an inch from the skin edge. December 22 and 23 he was given twenty-five minutes' exposure to a low tube at five inches. December 23 block excised. December 29 block excised. From December 29 to January 2 he was given daily twenty minutes' exposure to a low tube at five inches, and blocks were removed every other day until the whole fungus part of tumor had been softened and came away. In all, seven blocks were secured, covering the time from the fifth exposure up to the eighteenth, in all, thirty-six days.

HISTOLOGIC CHANGES NOTED.

Each block was cut in three portions and fixed in different fixatives. Hermann, Mann, Zenker and 25 per cent. formalin being used. The blocks were carried up, embedded in paraffin and cut in sections of from three to ten microns in thickness. The sections were examined unstained from the Hermann fixative for fat, and others were stained in various ways. The Hermann sections were washed in ether to differentiate fat from other substances taking osmic acid. Hematoxylin and eosin, hematoxylin and Van Gieson, Weigert's resorcin stain for elastic fibers, and Pianese IIIb for degenerations, Plimmer's stain for parasites were used. By these methods quite a number of changes could be made out, which can be briefly tabulated as follows:

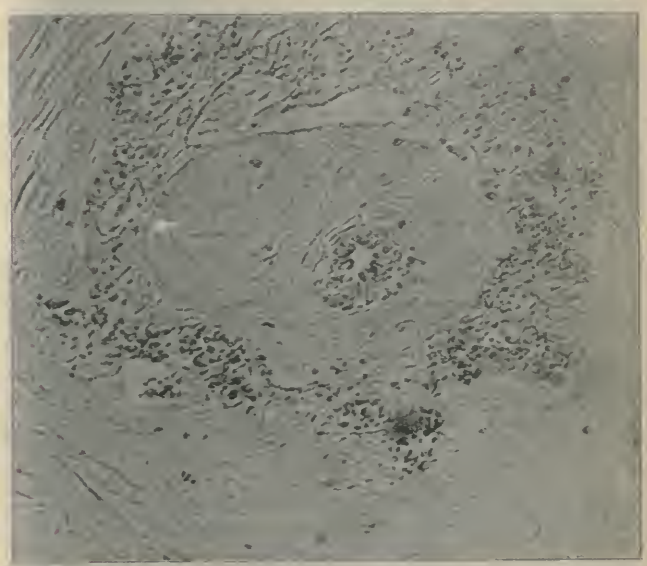

Fig. 4.—Circle of new vessels in epithelial pearl.

1. *Fatty Degeneration.*—This is marked in all sections from all blocks. In the early sections it is most marked in the epithelial cells at the periphery of the pearls, the fat occurring as granules grouped about the nucleus, and in many cases in the nucleus itself. Fat exists, however, in a large percentage of the epithelial cells, and this infiltration seems to increase with the number of exposures to the *x*-ray, until the cells disintegrate, when in the final stage of detritus it is seen mainly in the leucocytes, either as a degeneration, or possibly as a phagocytic inclusion.

In view of Unna's statement that fatty degeneration does not occur in epitheliomata, this is certainly a noteworthy effect of the treatment.

2. *Vascular Changes.*—In the earliest slides there are marked evidences of the formation of new blood vessels. They are seen between the epithelial cells and noticeably in the centers of many pearls. They are at first filled with red blood cells with an occasional white cell, but later the red cells disappear and the vessels are packed tightly with the polymorphonuclear leucocytes. These leucocytes are also seen between the epithelial cells, and

finally separate them into bands and detached cells surrounded by a reticulum filled by white cells.

3. *Elastic Tissue.*—Weigert's resorcin stain shows considerable elastic tissue in fibers and granules, usually in the immediate neighborhood of a new vessel, but not in its walls.

4. *Hyaline Degeneration.*—As this degeneration is a regular part of the life history of an epithelioma, it is not surprising that it should form a large part of the picture in many of the sections. It is especially noticeable in both pearls and single cells about the middle of the series, being replaced by coagulation necrosis in the latest slides. In many of the later slides the hyaline bodies of Unna are plentiful, as well as many cell inclusions, which, stained by the Pianese IIIb, or by Plimmer's method, are indistinguishable from the so-called Plimmer and Russell bodies as figured by Gaylord. As these do not appear in the early sections, but only when karyokinesis has ceased and degeneration of various kinds are very marked, it is difficult to understand how these fuchsin bodies can have any etiologic relation to cancer. They are indistinguishable as to staining reactions from the other hyaline bodies noted above.

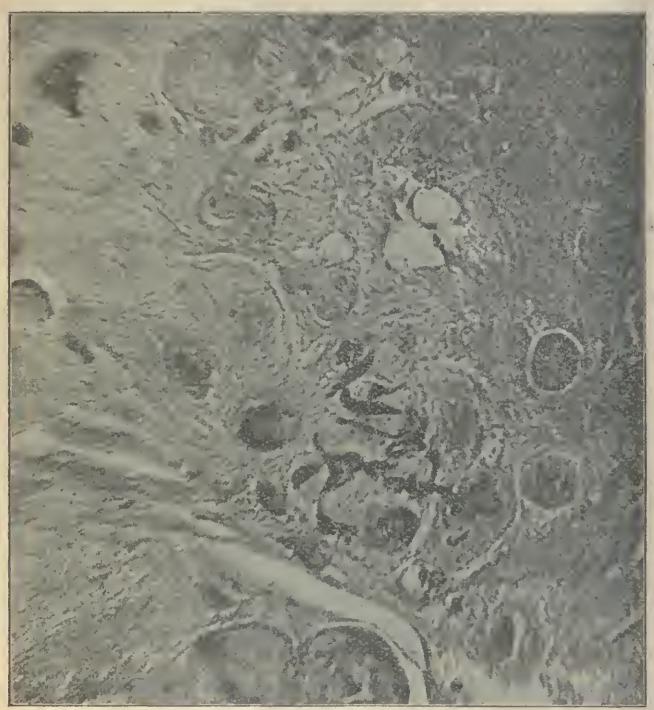

Fig. 5.—Elastic tissue. Weigert resorcin-safranin.

5. *Necrotic Changes in Cells.*—In some of the early slides karyokinesis is well marked, but later it entirely disappears, except an occasional cell in blocks taken from near the skin border of the ulcer. Chromatolysis begins quite early and increases until in the last sections there is hardly an intact nucleus. At the same time there is fusion of the cell bodies and loss of all cell outlines. Hyaline degeneration of single cells is very common, as before stated, as are the fuchsin bodies.

6. *Final Result.*—The latest sections obtained before destruction and liquefaction show an interesting and remarkable picture. Nothing is left of the epithelial structure but some dimly staining masses of cells in coagulation necrosis, with the rest of the section composed of a fine reticulum taking the acid stain, having its spaces filled with polymorphonuclear leucocytes, fragmented nuclei and other detritus, while interspersed through the mass are small clumps of epithelium and single cells, which have no nucleus and have lost their outline, and are just ready to pass into coagulation necrosis. In areas where the final fluid detritus was confined the microscopic appearance was like a so-called laudable pus, and the microscope showed only polymorphonuclear leucocytes, broken-down epithelia and free fat.

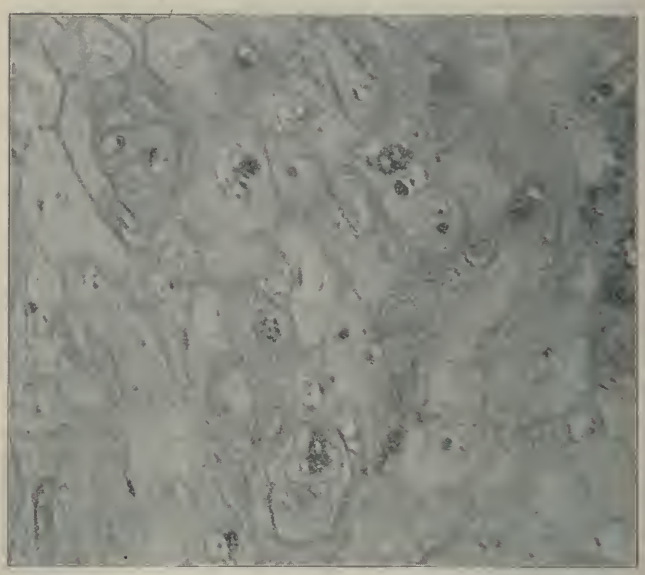

Fig. 6.—Shows hyaline cell inclusion similar to Plimmer bodies.

The study of sections from other epitheliomata, after varying exposure, gave results corresponding to the above, although in small growths it was impossible to get more than one or two blocks. One case especially, an epithelioma of the ear, after four ten-minute exposures, gave a picture like the final one from Case 1, except that the leucocytic infiltration was almost entirely composed of plasma cells, instead of the polymorphonuclear form.

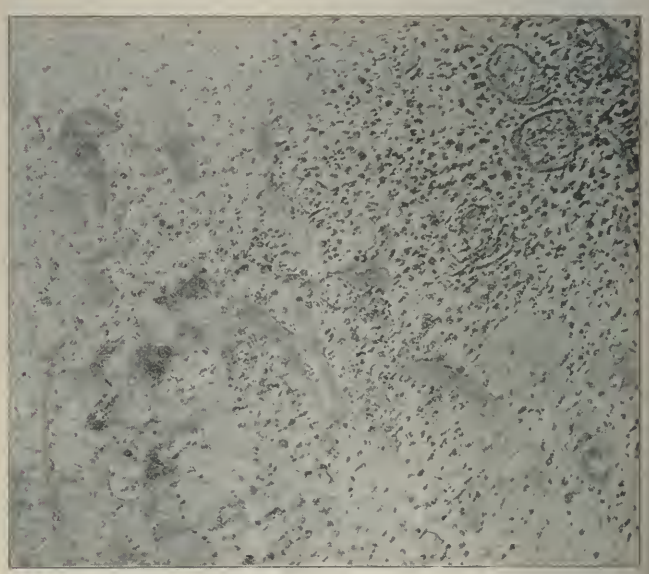

Fig. 7.—Shows general breaking down with infiltration of leucocytes into and between the epithelial cells, hyaline degeneration of the cells and at outer edge coagulation necrosis of whole mass.

It will be noticed that there are several very striking differences between the results of the study noted above, and those obtained by Ellis in the two cases of epithelio-

ma studied by him. These are the vascularization and the leucocytic infiltration which are probably only phases of the same process, and the difference was probably due to the destructive effect of the treatment in my cases, as compared with the negative clinical effects noted by him.

Certainly his explanation of the resistant character of the pearls, preventing curative effects, seems doubtful, at least, in view of the very early and decided changes in them noted above.

The explanations offered by some writers that the degenerations observed and final necrosis are due to decreased blood supply, which is caused by the thickening of the inner coats of the blood vessels, find no support in this study, as the abundant formation of new vessels and their distension makes improbable any obliteration of the different vessels. Unfortunately, none of the sections cut were from locations which could give any information as to whether the endarteritis observed by so many was present.

It seems probable that different epitheliomata may offer different degrees of resistance to the disintegrating effects of the *x*-ray, just as their bearers may show different degrees of susceptibility to the burning effects of the ray, but when necrosis is finally attained there will be characteristic changes in the cells.

It is to be regretted that sections were not taken from Case 1 before treatment, and more frequently during the active treatment, but the idea of making a study of the case occurred only when rapid results began to be noted after four treatments, and the subsequent progress was so rapid that all available tissue was destroyed when the seven blocks were obtained.

It may be of interest to hear the subsequent history of this case which began so auspiciously. Early in January, after some six weeks of treatment, all the elevated portion of the growth was destroyed and there was left a deep portion which extended into the bones of the carpus, and under the small tendons of the thumb toward the wrist. After wasting a great deal of time in a vain attempt to cause necrosis of the deeper parts, a small, apparently new growth was noticed at the radial edge of the ulcer. This determined an erasion under an anesthetic, which showed that the growth had progressed under the skin at the radial edge of the ulcer, in spite of vigorous *x*-ray treatment. All the epithelioma was carefully scraped away, and all overlying skin was excised, as well as the small extensor tendons of the thumb, which were hopelessly involved, and there is now a clean defect, with no signs of epithelioma, which is healing rapidly under mild *x*-ray treatment.

The tissues excised, which included nerves, tendons, vessels and new-formed scar, all exposed to many *x*-ray treatments, will furnish material for a later communication.

CONCLUSIONS.

1. It is probable that when epitheliomata react favorably to *x*-ray treatment that characteristic histologic changes will be found.

2. The important early changes are fatty degeneration and vascularization of the epithelial pearls.

3. Leucocytic infiltration and various degeneration processes complete the destruction.

4. Bodies indistinguishable from "Plimmer's bodies" multiply as epithelia degenerate.

NOTE.—I wish to acknowledge with thanks the aid in this study of Prof. Margaret S. Nickerson, Drs. Louis B. Wilson and Arthur T. Mann, without whose assistance the work would have been impossible.

DISCUSSION

ON PAPERS OF DRS. WILLARD AND STEWART.

DR. HENRY A. CHRISTIAN, Boston—I wish to add one case to the report of Dr. Stewart, a case of epithelioma of the back of the hand of the distinct cauliflower type. Before any treatment was undertaken a portion of the tumor was excised and sent to the pathologic laboratory of the Boston City Hospital for examination. It was a typical specimen of epithelioma, with the usual cell nests and with no particularly marked amount of inflammatory reaction. After treatment for a considerable length of time a second portion was excised. Pathologic examination of this showed that the epithelial cells in the cell nests were dead. They no longer stained and, what is particularly interesting, they were in many places surrounded by foreign body giant cells. In other words, the dead epithelial cells had changed from a living acting part of the growth and now simply acted as a foreign body and were being destroyed by the giant cells. There were no polymorphonuclear leucocytes present. There was no change in the connective tissue cells, while the epithelial cells were entirely dead.

Another point of interest was that a portion of the hand protected by the lead shield and supposed to be non-carcinomatous, i. e., to lie beyond the border of the growth, was in reality carcinomatous. This portion protected from the *x*-rays by the lead shield showed no such change. In other words, the epithelioma survived where the lead shield protected the growth; and there was death of the cells where the lead shield did not protect it.

Just what the process in these cases is I am not prepared to say. I do not think that too much importance should be placed on the fatty degeneration described by Dr. Stewart. Fatty degeneration has, so to speak, lost in recent years some of its pathologic standing. We no longer look on it as such an important degenerative process. Then, fat is frequently present in cells of the body under normal circumstances. Furthermore, the reagents used by Dr. Stewart for obtaining the reaction demonstrating fat are open to some objection. The main reagent used was osmic acid. We know that osmic acid stains other things than fat, for instance, certain keratin granules in the epithelial cells of the skin, also, the fatty substance of the sebaceous glands. Now, as the epithelioma originates from the skin these substances normally present must be borne in mind. If a substance stains black with osmic acid, this is not positive proof that it is fat, nor is the presence of fat always evidence of a degeneration.

Another interesting point is the presence of fat in the polymorphonuclear leucocytes. This occurs very frequently; in fact, it is generally present where there is an inflammatory process. It is also to be found in the polymorphonuclear leucocytes circulating in the blood. This is true particularly where there is a marked leucocytosis. I have had an opportunity to study these cells, particularly in association with pneumonia, and have found fat very constantly present in them.

Another point on which emphasis was laid is the great number of polymorphonuclear leucocytes present in this case. Is that due to the effect of the *x*-ray or to something else? In this case I understood that the surface skin was ulcerated. In such a condition you would expect to find polymorphonuclear leucocytes present at the outset. Again, when we have polymorphonuclear leucocytes and an inflammatory process we generally have the formation of granulation tissue; in other words, the formation of new blood vessels, so that the statement that the formation of new blood vessels is caused by the *x*-ray is possibly also open to criticism. I think the fact that the epithelial cells are dead, as shown by the case reported by Dr. Stewart and the case I have reported, are rather important factors. It is possible that simple inflammation may have had something to do with the formation of the polymorphonuclear leucocytes and the new formed blood vessels. The question remains open as to how far fatty degeneration, inflammation and cell death are due directly to *x*-ray action. Very general conclusions are not, of course, to be drawn from single cases.

DR. EDWARD H. NICHOLS, Boston—I agree with the beginning of Dr. Stewart's paper, but there are one or two things later on which I am compelled to differ with him. In regard to those lesions which were selected for this *x*-ray treatment as epidermoid cancer or epithelioma, which, after a greater or lesser number of treatments, have disappeared, the ulcers healed over, the capillary growth melted down and entirely disappeared and new skin formed, such cases are constantly being reported as cured. I think we should consider all those statements of cures with the greatest suspicion. It is true that for some reason or other the surface condition has apparently improved. The fact that the new skin has formed over the area of the wound is far from proving a cure of that case of cancer. I have had considerable opportunity during the last three years of observing the histologic changes following *x*-ray work. The cases referred to by Dr. Christian I have had the opportunity of seeing. The changes as we have seen them following the use of the *x*-ray have shown no peculiar characteristics. The changes in cases of epidermoid cancer treated by the *x*-ray show, as a rule, an increase, and in many cases stimulation of the cells. And I would defy anybody to recognize this change as a characteristic one. You see exactly the same changes as you would see in cases of degenerative carcinoma, and this has been deemed by some men to be due to the action of the *x*-ray on certain portions of the epidermoid growth, but they are really indications of the growth of the cancer. The *x*-ray acts as an irritant, and acts on those portions of the cancerous growth which are less resistant than the sound tissue. I think it can be perfectly explained by saying that the *x*-ray acts as a mild irritant, not producing burns, yet sufficient to cause increase in the epithelial cells at first and later disintegration. One other thing that needs to be borne in mind is that the *x*-ray can also produce epidermoid cancer. At a meeting of the American Dermatological Association a year ago last August, a case was reported of extensive epidermoid cancer of the hands of a man who had been using the *x*-ray, followed rapidly by metastasis. There is at the present time an operator in Boston who has lost three fingers on one hand and two on the other due to extensive epidermoid following rapidly after very extensive *x*-ray irritation, he having had a distinct *x*-ray burn. In regard to the bodies that Dr. Stewart mentioned, I have seen their work in their own laboratories, so perhaps I can express an opinion, and I have seen the definite Plimmer bodies of Greenough, and I do not think these objects seen by Dr. Stewart were the Plimmer bodies. I think every surgeon should bear in mind very carefully the fact that the *x*-ray is liable to produce cancer. In certain cases it may do good, and for that reason I think it is better to first remove the epidermoid cancer and then use the *x*-ray, and in certain cases it may be of advantage, but I think in all cases operative treatment should be the first procedure.

DR. JOHN RIDLON, Chicago—In regard to the treatment of tuberculosis of the joints by sunlight, I do not think that we should assume too large a hope in this direction. Sunlight or any other light alone does not cure tubercular joints; they must be treated by mechanical means, immobilized, or else no good can result from the exposure to the sunlight or any other light. As to the effect of sunlight on tuberculosis of the joints, I am somewhat in doubt as to whether it is likely of itself to produce beneficial results. All of us who practice in large cities and large towns can see great gain if a child is exposed to the sunlight. On the other hand, in the case of tubercular joints in the children of farmers and people who live in the country, who are more exposed in the sunlight and fresh air, there is usually not so much improvement from further exposure to sunlight and open air. It would seem then that from clinical observation it is the change of environment that has the effect rather than the sunlight and air without the local environment.

I have had no personal experience with the *x*-ray treatment of tuberculosis. My office associates, Dr. A. D. Harmer and Dr. John L. Porter, have done considerable experimental work with the *x*-ray on tuberculosis of the joints, and such cases as we three together had that seemed to be favorable for experimental work we have subjected to that treatment. The cases were those in which the progress had been unfavorable under ordinary mechanical fixation. It was thought only fair that such cases should be selected and not those which were doing well under ordinary treatment. A considerable number have been subjected, during the last year and a half, to the *x*-ray treatment. Many have improved more rapidly than could have been expected without this treatment. The number, however, has not been sufficiently great for us to form any trustworthy conclusions. It has reminded me very much of the iodoform injection treatment, which was very much in vogue about ten years ago. Almost all of us used these injections of iodoform in the cases of tuberculosis, and we all thought that we were getting better results.. We all know now that the injection of iodoform into tuberculosis of the joints is practically useless. So I fear that this *x*-ray work will turn out in the same way, and that, although a certain number of those cases do appear to be cured, it will not amount to very much. What we have learned is that when the superficial joints are benefited by the *x*-ray there must be very marked irritation of the skin. Tuberculosis of the hip joint and of the spine have not been benefited. Dr. Harmer has deliberately burned the skin in many cases, and he has found that he does not get as good results when the skin is not subjected to strong irritation.

DR. FRED. B. LUND, Boston—I have seen, during the past five years, cases of cancer treated by the *x*-ray. Surgeons recognize that epithelioma of the face, particularly of the rodent ulcer type, is a non-malignant form, that recurrence is slow, and that in the cases that have recurred there has usually been no glandular involvement. I have seen a great many cases of cancer of the face, many of the rodent ulcer type, that were really benefited by the *x*-ray treatment, and leave a most excellent scar, and some of our surgeons in Boston have stated (very prematurely, it seems to me) that the day of the knife in the treatment of epithelioma was past, and that we had no business to use the knife in those cases, but that they should be turned over to the *x*-ray treatment. On the other hand, I have seen some very sad results following that advice. A patient came in suffering with an epithelioma of the lip in a very early stage. Glandular involvement appeared soon after it was exposed to the *x*-ray, and he was treated by the *x*-ray without the slightest results. I have seen a number of cases of recurrent carcinoma in the breast glands treated without the slightest result. There are a certain number of cases of epithelioma of the face, of the more malignant type, in which it is of no value. I operated three years ago on an old lady 68 years of age. The cancer was excised and the wound covered with skin grafts; excellent results followed for a time. Then recurrence took place, and I excised the growth under local anesthesia. After operating on her 12 or 15 times, I tried the *x*-ray treatment for six months. At the end of this time the growth recurred with extraordinary rapidity, and the soft parts of the nose had to be excised down to the nasal bones. In other words, it seems to me that the *x*-ray is in the nature of a mild irritant or caustic, that it has an excellent influence on non-malignant growths, but that the malignant growths had better be excised. The ideal way perhaps is to first excise the growth and then in case of recurrence use the *x*-ray, but temporizing with the *x*-ray in the first instance is not only useless, but dangerous.

DR. JOHN W. BRANDAU, Clarksville, Tenn.—Is there any effect produced on the kidneys by the use of the *x*-ray in cancer of the cervix? In the past few months I have treated two cases of carcinoma of the cervix. One was of the cauliflower type, the other hard cancer. I had excellent results in both so far as the cancer was concerned. The cauliflower cancer underwent rapid degeneration, and after ten treatments of fifteen minutes each every second day the cervix was practically normal in size. In the other case the effect was very different. There was sloughing of the cervix after seventeen treatments covering a period of three months. In

both cases the pain was extreme previous to treatments; opium in some form being administered. After the second exposure there was no more need for opium. One of the women went to her home apparently cured of the cancer to await the results of the sloughing, with instructions to return in the course of three or four weeks for examination. In about four weeks there was suddenly almost complete suppression of urine, which was highly laden with albumin. In a few days she died from uremia poisoning. The other case died about eight weeks after treatment was discontinued from exactly the same cause, and what little urine I could get by catheterization was almost solidified by albumin on boiling. I would like to know whether any of the other gentlemen present have observed any bad effects on the kidneys from this treatment.

DR. J. E. THOMPSON, Galveston, Tex.—A few months ago a young man 29 years of age, with a large tumor over the stomach, was operated on, and it was found that the entire anterior part of the stomach and the lesser curvature was involved with a growth that afterward proved to be an epithelioma. There was almost complete obstruction of the pylorus for several weeks before the operation. I did a posterior gastroenterostomy and got immediate relief of the symptoms of obstruction. The growth appeared to be an extensive one, and about three days after the operation it occurred to us that it might be well to try the effect of the *x*-ray on this tumor. About forty-eight hours after the operation, I believe, we reopened the wound and packed the opening between the peritoneal parieties and the tumor, leaving this mass, which was about the size of a large orange, in the wound. We got profuse exudate. After 24 hours it ceased. We took out our own packing and found that the mass had been transformed into an external one. We then commenced the use of the *x*-ray, and after having used it for about a week, we noticed signs of increase in size, and a few days later the mass broke down and discharged profusely a cheesy matter mixed with pus. It then became apparent to us that we were going to have a fistula, because sloughing was extensive, and a few hours later, the nurse came to me and informed me that there was something in Mr. A.'s bed that looked like his breakfast. We found this to be true. A large opening was found in the stomach. We succeeded in packing this off, so that the patient could retain food sufficiently long to pass through our very large anastomosis into the bowel. He went to bed, was comfortable, took his nourishment well and enjoyed it. He seemed to have an especial liking for such indigestible foods as ham and bacon. He improved slightly in weight for two or three weeks, when he began to go down, and after about a month died from extreme emaciation. This, to my mind, seems to teach us some very interesting points. One is that we can not break down hard epithelioma with the *x*-ray. The second is that it is rather dangerous to try to break down a cancerous growth in the abdominal cavity. Third, the *x*-ray did not appear to have any prominent effect in checking the general growth of the epithelioma, which had become metastatic at the time of the operation.

DR. DE FOREST WILLARD, Philadelphia.—In answer to the question as to whether a blue medium is of value either with the *x*-ray or with the Finsen light, or with sunlight, it seems to me to depend entirely on the power of the medium to increase the force of the ultra-violet rays. Since the ultra-violet rays are therapeutically the potent ones, of course, the larger the proportion the better will be the result. The rays have proven themselves of value already in superficial tuberculosis and cancer, but we have by no means achieved the limit of possibility in the use of the sun's rays. I stated in my paper that we should use these agents as supplementary to our general treatment and not depend on them entirely. In regard to the use of the *x*-ray in tuberculosis, the benefit has certainly been sufficient to encourage me to use it further. Its influence in cancer and epithelioma has in my hand been helpful, but not curative. The Finsen light and the *x*-ray are still only in the experimental stage, and I have no anticipation that they will do more than act as accessories to general treatment. I expect to test them for five years. I do not expect to obtain any results that will be of value in a shorter time.

In reply to Dr. Ridlon, I would say that in my conclusions, I stated that sunlight and fresh air should be employed, "together with fixation of the joints." In another conclusion I said that this method should be employed, "not to supersede, but to supplement the mechanical and operative appliances." I took it for granted that no element would be neglected, and particularly the mechanical fixation, which is so important, in fact the most important element in inhibiting a destructive tubercular process.

In regard to the criticism that many farmer's children who live in the open air have tuberculosis of the joints, I would say that I have not infrequently found farmers houses in far more unsanitary conditions than prevail in the city.

Our patients are benefited in the city hospitals largely because we bring them out of the darkness, and give them good food, in addition to mechanical appliances.

The point that I wished to emphasize was that, in addition to all our other methods, we should employ sunlight, the *x*-ray and the Finsen ray, in fact everything that will help us in the desperate fight with joint tuberculosis.

DR. J. CLARK STEWART, Minneapolis—In answer to Dr. Christian I would like the permission of the chair to ask him a question, and that is, whether the washing of sections stained by osmic acid in ether and thus discharging the black color does not prove the blackened substance to be fat. The technical work was done for me by Prof. Margaret Nickerson of the University of Minnesota, and I am confident that Dr. Christian may accept all statements of fact as correct. In regard to the fatty degeneration, as I stated in my paper, the slides were washed with ether, demonstrating the presence of large amounts of fatty degeneration, and as Unna states that fatty degeneration never occurs in epithelioma, this pronounced fatty degeneration was considered worthy of mention. In regard to the vascularization being simply that of granulation tissue, I would say that the presence of the vessels long antedated the presence of anything which could be termed granulation tissue, and even of the leucocytes themselves. Later, where at first red blood cells had appeared in the new vessels, these were crowded with leucocytes, and still later, the leucocytes infiltrated the extravascular tissue. All the changes described in my paper were distinctly progressive during the treatment of the case. I don't attach much importance to the polymorphonuclear form of leucocytes in these sections as in two other cases where the resulting changes were about the same, the leucocytes were entirely of the plasma cell type. I was glad to hear Dr. Nicholls' remarks about the nonoccurrence of Plimmer's bodies in epithelioma. The bodies figured by me closely resemble those pictured by Gaylord in his article in the *American Journal of Medical Sciences*. The study of these cases shows certain positive results which must be of more or less value in explaining the results attained by successful treatment.

In regard to Dr. Willard's paper I can add just one observation of interest. I have treated one case of caries sicca of the shoulder joint with rather striking results. These cases, as you know, usually go on to ankylosis after about two years' disability, while the case under consideration attained about the same result after two months' treatment with the *x*-ray. Apparently the cicatrization and contraction of the tubercular tissue about this joint was very greatly hastened by the effect of the *x*-ray.

English the Universal Language.—A Spanish physician taking a post-graduate course at Vienna writes to the Madrid *Siglo Medico* that he had been informed that some of the lectures were delivered there in French and other languages, but found that this was a mistake. He says: "The lectures are exclusively in German or in English, and the latter is the truly universal language, and he who says the contrary, lies. (". . . *y en ingles, que es hoy el idioma verdaderamente universal: y el que dijera lo contrario miente.*") He adds that the North American colony there is "tremendous," and "Yanquis" are to be met everywhere, very frequently as the assistants at operations.

VARIX OF THE INFERIOR MESENTERIC VEIN COMPLICATED BY CHRONIC ULCERATIVE COLITIS—OPERATIONS.*

J. E. SUMMERS, JR., M.D.
OMAHA.

I am led to report the following case because the condition found is unusual, or has at least received scant attention at the hands of pathologists. For this reason I will give the history somewhat in detail.

History.—Mr. B., 34 years of age, was referred by Dr. I. Lukens of Tekamah, Neb. The following was elicited: When two years of age he began to suffer from prolapsus of the rectum and never received permanent relief of this condition until 27 years old. He was a rather puny boy and was not a robust man, although able to attend school and perfect his studies so as to become a competent school teacher. During all these years there had been a constant tendency toward rectal prolapse.

When 27 years old Mr. B. underwent an operation, some tumors were removed (probably hemorrhoids), three ligatures being employed. Following the operation the patient enjoyed fairly good health until the spring of 1901, when his general health became poor. In August, 1902, as the result of doing some unusual manual labor, the lifting of heavy joists, he was attacked with frequent desire to go to stool and the passing of considerable quantities of mucus and blood. During several days the mucous bloody discharges alternated with the passing of hardened feces; this condition was succeeded by an attack of diarrhea. Because of poor control of the bowels a pad had been worn continuously to prevent soiling by the discharges. The alternating attacks of constipation and mucous discharges continued from August, 1901, to March, 1902 when the man came under my care in the Clarkson Hospital.

At this time Mr. B. had the appearance of ill health, and poor nutrition; on examination the anal sphincter was found weak and incompetent, the rectum to the touch and by inspection was the seat of five ulcerations of different sizes, one being as large as a silver dollar and the others smaller. On introducing the sigmoidoscope numerous ulcerated patches were observed in the sigmoid. The edges of all ulcerations were elevated, and where palpable were, together with their bases, rather indurated; the surfaces were pale.

The treatment ordered was irrigation of the bowel, with bland or stimulating solutions of salt and silver nitrate; the recumbent position was insisted on and a restricted but nutritious diet prescribed. Little improvement followed this practice, although with some minor alterations it was kept up from March 13 until June 2. At this time I decided to do a left inguinal colostomy for the purpose of giving rest to the ulcerated sigmoid and rectum, as well as to admit of more positive local treatment.

Operation.—On opening the abdomen a surprising condition was revealed, the inferior mesenteric vein was very much enlarged and its walls thickened. All of its branches as far as they could be inspected were uniformly in the same strikingly swollen shape. Although I then realized that a colostomy would do little good the gut was fastened to the abdominal walls. After thinking the case over for a couple of days, I loosened the unopened gut and returned it into the abdomen.

Two months' further trial with local, dietetic and medicinal measures, there being no improvement, I opened the abdomen to determine whether or no there could be discovered in the pancreas or elsewhere along the route of the inferior mesenteric vein, an enlargement or interference by pressure on the vein near its entrance into the splenic vein. Nothing strikingly unusual was discovered about the pancreas except that it was thicker than normal and not quite so fixed. However, a considerably dilated stomach was found, and thinking this might, by dragging, possibly produce some interference or kinking in the circulation of the veins, a gastroplication was carried out after the manner of Moynihan. A Morrison operation was also done with the hope of relieving the portal system, and in this way lessening the congestion in the inferior mesenteric vein. My patient was much improved by these procedures; he gained in weight and his symptoms were better, but he was still an invalid. Two months later I established an artificial valvular fistula in the cecum for the purpose of complete, direct irrigation of the entire large bowel. Great improvement resulted from this last practice, the patient gaining 20 pounds during the next two months. There still was at that time some slight mucous discharge. I sent the man home, his many months' care at my hands having ended in a remarkably improved state. He was instructed to keep up the daily local treatment. A recent letter tells that he has allowed the fistula to close and that he is beginning to relapse. I have never seen such a uniform chronic enlargement of veins.

When we recall the fact that the inferior mesenteric vein passes under the pancreas on its way to empty into the splenic vein, and the many pathologic, as well as congenital, alterations that may be found in the pancreas, possibly the observations made at the time of operation would be sufficient to account for the varix. From this point of view, reasoning from everyday experience in varicose ulcers of the lower extremities, the ulcerated bowel must be looked on as secondary to the varix of the inferior mesenteric vein. From the point of view, however, of the fact that veins carrying blood from chronically inflamed areas sometimes participate in the changes incident to the inflammatory process, we might reasonably conclude that the varix was in part the result of the long-continued prolapsus of the rectum, and the accompanying ulcerations of both the rectum and sigmoid, and probably of the descending colon also. All other veins in the abdomen were apparently normal. The only organs whose size and position were found abnormal were the stomach and pancreas.

During the past year I have had a case of chronic ulcerative colitis, which I have cured by means of an artificial valvular fistula in the cecum. In both cases I established an opening for a 30 F. catheter, in order that I might employ a reasonably good-sized flushing stream. The use of the open appendix as a channel for irrigation seems to me like using a toy pistol when an efficient firearm is essential. It is an unusually large appendix that can carry an 8 F. or 10 F. catheter, both too small for other than dribbling irrigation. I must acknowledge that some distinguished authorities have found this, the appendix channel, useful. In my cases I believe I did better by my patients in removing the appendix from each.

DISCUSSION.

DR. F. D. SMYTHE, Memphis, Tenn.—The custom has been recently adopted at the hospital where I am attending surgeon to refer the cases of chronic colitis entering the service promptly to the surgeon for operation and treatment for the reason that medical treatment heretofore has proven unsatisfactory. It was formerly our custom to resort to dilatation of the sphincter and irrigation of the colon followed by application of silver nitrate. Improvement usually followed such a course, but the patient soon relapsed, necessitating a repetition of the treatment, the patient almost always finally dying or drifting to another physician to undergo a similar treatment, with no better result.

Dr. Goltman, Memphis, at a meeting some months ago, detailed a course of treatment that he used for acute dysentery, the main feature of which was the dilatation of the sphincter under anesthesia, which treatment he asserts is sufficient in his hands. I have never employed this method.

The plan adopted by Dr. Summers in the treatment of his case is the same that I have employed for some time and with

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

very gratifying results. I always make a good opening in order to introduce with ease a large tube for irrigation, paying no attention whatever to the appendix unless it is to effect its removal if time is not too much of a consideration. Such cases should be treated on surgical principles, thoroughly cleansed, rest of the part and attention to the diet. By such a course we have accomplished far more than was possible by medical treatment alone.

DR. SAMUEL E. MILLIKEN, Dallas, Texas.—Ulcerative colitis is one of our prevalent maladies. When Dr. Weir, New York, suggested last year at the session of the American Medical Association the use of the superfluous appendix as a means through which to reach the lower bowel, I was in hopes that I would have an opportunity of applying this method of treatment to some of our cases of ulcerative colitis, but up to the present time I have had no such opportunity. I have resorted to the various medicaments through the rectum and with varied and unsatisfactory results. I am glad to hear that there are better methods than those suggested by Dr. Weir. The methods suggested by Dr. Summers and the last speaker, i. e., the establishment of a fistula in the anterior wall of the cecum will possibly give more direct connection than the simple appendiceal method. I regret that an opportunity has not been afforded me to follow the suggestion, but it seems to me that this is a logical means of remedying what is with us a rather prevalent condition. Like the last speaker, I know nothing of the pathology which has led up to this condition.

DR. JOHN E. SUMMERS, JR., Omaha—I hoped that some one would say something about the anomalies of the pancreas or its changes in position. As the inferior mesenteric vein runs under the pancreas to empty into the splenic vein, which lies in a groove in the under surface of the pancreas, an obstruction in the return flow in the inferior mesenteric vein can be well imagined, provided there be an abnormality in the pancreas. I do not know what it was, but it seemed to me that, in this particular case, there was something unusual developed in the posterior area of the pancreas, and that this caused continuous interference with the current in the inferior mesenteric vein with the resultant varicosity. I merely mentioned the vermiform appendix as a route for the irrigation of the colon, as I had been impressed that Dr. Weir had advocated it as a kind of surgical joke. In the discussions of the surgical section of the New York Academy of Medicine, it will be noted that one or two surgeons have advocated this appendix route and have reported satisfactory results. One of these gentlemen stated that by dilatation one could succeed in getting the appendix to carry a No. 10 F. catheter. Everyone knows that such a caliber is too small for flushing purposes. When you want to flush out a cavity you must have a current and, therefore, I think a 30 F. catheter or 40 F. catheter none too large. You can remove the catheter, introducing it only when the bowel is to be irrigated. If the operation has been well done there will be no leakage.

CONGENITAL DISLOCATIONS OF THE RADIUS.*

CHARLES A. POWERS, A.M., M.D.

Professor of Surgery in the University of Denver; Surgeon to St. Luke's Hospital.

DENVER.

History.—In November, 1902, X. Z., a boy of 13 years, was brought to my office. Three days after his birth disability and deformity were noticed at the left elbow and in the left hand. In early life the general use of the limb was practically the same as at present. As years have gone by the limb has become neither more nor less useful.

Examination.—The left upper extremity is materially shorter than its fellow. The left forearm is in extreme pronation; it can be supinated but very little, the lower end of the radius moving but slightly on the ulna. As the limb hangs by the side the back of the hand looks forward and inward. If the boy is asked to flex the elbow he does it by abducting the arm to 45 degrees and throwing it forcibly forward. With the hand on the abdomen and chest he can then flex the elbow to 90 degrees, but not further. Flexion of the fingers is fairly good; extension is weak and imperfect. The thumb is flexed and adducted in the palm of the extended hand, being rotated somewhat out. Flexion of the fingers is made over this palmar-flexed thumb. When offered a coin the boy lifts the arm, rotates it in and throws the palm of the hand inward, then outward and forward to receive it. He makes no ordinary gestures in attempting to receive proffered articles. He uses the affected hand but little.

The elongated left radius is dislocated upward, forward and outward, lying on the outer and anterior aspect of the humerus. The condition is shown in the accompanying *x*-ray picture and in the photographs. Measurements are as follows:

Circumference of the right arm at its middle, 7½ in.; of the left arm at its middle, 6½ in. Circumference of the right forearm 2½ inches below the elbow is 7½ in.; at the same point on the opposite side it is 6 in. The right upper extremity from the tip of the acromion to the tip of the middle finger is 25 in. long; on the left or affected side it is 20½ in. long. With the elbow flexed the right arm measures 11½ in. from the tip of the acromion to the olecranon, on the opposite side it measures 10½ in. The right ulna is 8¼ in. long, the left ulna has a length of 6¾ in. The cup-shaped upper surface of the radial head is plainly felt, some 1⅛ in. above its normal. It can be satisfactorily palpated. It seems to be of normal size. It rests anteriorly on the external humeral ridge. The bones below seem to be normal in shape. Innervation of the extremity is good.

The boy is otherwise normal; his mental condition is excellent. His general appearance is that of boys of his age.

The boy was brought with a view to determining whether he would be apt to be helped by an operation. At first thought I felt that resection of the upper end of the radius would permit freer motion. However, on considering that the condition was due to defective construction, that the entire limb was imperfect and that the hand was deformed as well as the elbow, it seemed probable that any operative procedure would be tentative. The parents declined operation unless given a fairly positive assurance.

So few cases of this affection have been observed and reported that one is destitute of data on which to form an opinion as to the value of operation. Thus, while various observers have noted the pathologic condition postmortem or have described the symptoms in living cases, I am unable to find but three instances in which recourse was had to operation. (*Vide infra* for question as to the authenticity of the second of these.)

Langenbeck in 1865 made a simple resection of the entire left elbow of a 6-year-old patient of Mitscherlich.[10] No result was observed, as the child died some weeks after operation.

Bessel-Hagen[20] made a simple resection of the head of the radius with the best result.

He found the form of the radial head altered, almost spherical and smooth. The cartilaginous covering had disappeared in many places. The dislocated and badly deformed annular ligament covered the most external end of the bone like a distorted cap, partly bound to it by fibrous strings. Bessel-Hagen did not anticipate a successful result, and resorted to operation only after much persuasion. But happily after the operation the formerly half-flexed arm could be stretched out perfectly. Through methodical, energetic movements full supination was soon possible. Over a year after the operation the girl could perfectly stretch and bend and supinate and pronate the arm. The bones slid easily and

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

smoothly on each other, the sensitiveness had disappeared and strength for work was increased.

Bonnenberg[25] reports a case referred to him by Hoffa. I cite this at length as it is fully described by the author. The result is seen to be one of but moderate improvement. Further, the type of the affection approaches that observed by me.

The patient was a girl of 20 years. The right radius was dislocated forward. The right arm appeared shorter and weaker than the left, especially in the forearm. The forearm was in position of supination, the hand being dorsally flexed. While the radius approached the normal, the ulna was twisted in its lower part and in the upper and middle thirds was more convex than normal. The elbow joint could only be extended to an angle of 155 degrees. In the extended position was clearly felt the epicond. internus humeri, the point of the olecranon and the epicond. externus humeri. If the arm was flexed

Figure 1.

the head of the radius glided up on the anterior surface of the humerus. Pronation of the hand was not possible. The patient had worn apparatus which held the head of the radius firm, but its weight and pressure were annoying, and since an improvement through its use could be looked for only after a very long time the patient preferred operation, which was performed by Bonnenberg and Hoffa.

An incision about 6 cm. long was made on the outside of the elbow joint over the external condyle of the humerus, parallel with the long axis of the arm. The joint capsule was opened. The entire outer half of the lower end of the humerus was slightly concave, so that no clear limit existed between the eminentia capitata and the part of the epiphysis not covered with cartilage. The cartilaginous covering of the eminentia capitata reached about 2 cm. higher than normal. The outer edge of the lower end of the humerus appeared much thinned. In the curved lower part of the humerus the head of the radius lay over the eminentia capitata. It was completely covered with a fibrous capsule which was attached about the neck and was connected with the outer part of the joint. The capsule was split over the head, and after the periosteum was loosened a piece of the radius about 3 cm. in length was taken off, the cut surface smoothed and the radius passed under the eminentia capitata of the humerus. The capsule which covered the head of the radius was taken away. Flexion and extension of the elbow joint were now entirely unhindered. Not so, however, with pronation and supination. Therefore an incision about 4 cm. long was made over the styloid process of the ulna and after loosening up the periosteum a piece about 3.5 cm. long was taken from the lower end of this bone. Then pronation and supination were possible. Healing by granulation took place in about a month, when movements were begun. The arm was massaged daily. Electrical treatment. A little later, since there was still present the spiral twisting of the radius, osteotomy was performed between the middle

Figure 2.

and lower thirds. Again healing by granulation. When this was complete systematic attention to movement was given. At the end of a few months the condition was as follows:

The radius ends over the external condyle of the elbow; there is decided weakness of the right arm as compared with the left. Measurements: Right middle upper arm, 22 cm.; left middle upper arm, 26.5 cm.; thickest part of forearm, right, 20 cm.; left, 23 cm.

Voluntary pronation and supination are not possible on the affected side. The case may be said to be moderately improved. The piece that was taken from the upper end of the radius was 3 cm. long; the diameter at the head, 15 mm.; at the neck, 13 mm. Demarcation between the two was scarcely present. The head was defectively developed; it was infantile; it was lacking in cartilaginous covering except at a place on its posterior circumference about 1 cm. in diameter. Here the head of the radius glided over the anterior surface of the

humerus. A characteristic glenoid cavity was not present. Good pictures show the condition before and after operation.

Bonnenberg[25] collected 30 cases in 1893; of these 12 were double, 18 were single. Since that time the only observers of whom I can find record are Ambard,[23] Abbott[21] and Bergtold.[19] Ambard reported a double luxation in a man of 28 years who applied for treatment for excoriations of the external aspect of each elbow. Two very prominent protuberances on the outer part of each elbow were noted, which were brought into action by the different movements of the forearm. On looking at the posterior surface all of the middle and internal part appeared normal. But at the external view there was a prominence rounded over its lateral surface, flattened at its superior extremity. From in front the region of the elbow appeared normal. On palpation this bony

Figure 3.

prominence could only be considered as the upper extremity of the radius itself. In supination and pronation the radial cup could be rolled between the fingers; in flexion or extension it was lowered or raised. In spite of the abnormal situation the superior extremity of the radius was strongly connected with the other bones of the joint. All of the ordinary movements of the elbow, as well as the muscular force, were perfectly preserved. The length of each radius was 1 cm. more than that of the ulna, whereas normally the radius is 0.75 cm. shorter than the ulna. The ulna and humerus were normal. The two dislocations were absolutely symmetrical. The rest of the skeleton was normal, save that the two clavicles were prominent at the middle part. The nose was sunken in on account of caries of its bones and atrophy of the inferior turbinate; there were various ocular lesions pointing to hereditary syphilis.

The dislocations of the radii were noticed soon after birth. There was no family history of the trouble. The writer is inclined to think this patient a hereditary syphilitic, and thinks it possible (?) that the deformity was due to this trouble. Excellent radiographs are given.

Bergtold[19] gives an admirable account of a similar case, except that while flexion and extension were perfectly preserved the forearms were in extreme and fixed pronation. Abbott[22] reports on 9 cases, 7 of which occurred in one family, the cases having been scattered over four generations; 5 of the cases belonging to three generations had been examined personally by him, and all presented dislocation of the radius forward in one or both arms. Flexion and extension in all were free, but there was no movement of pronation or supination. In all the cases the deformity had caused the patient much inconvenience; no member of the family was the subject of any other deformity. Dissections of the elbows of the youngest of these cases were shown by Abbott at a meeting of the London Pathological Society, the chief abnormality in one being a large protuberance from the outer side of the coronoid process, fixed to the neck of the radius and possessing an extra center of ossification. The dissected elbows of a child of two months were shown. On the right side there was a dislocation of both bones directly backward, the articular end of the

Fig. 4.—Showing the position of the limb when the patient attempts to receive a proffered object.

humerus being deeply cleft and much altered in shape. On the left side the radius was dislocated backward, upward and inward, still keeping its normal relation to the ulna which articulated with a mass of cartilage attached to the lower part of the shaft of the humerus, representing the trochlea and internal condyle, the lower end of the humerus consisting only of external condyle and capitellum. In this case the prime trouble was evidently in the humerus. A living example of congenital dislocation of the left radius backward and outward in a girl of 21 years was also shown. The president of the society, Sir George Humphrey, thought that in all cases the displacement was slight, and that all seemed to be due to want of proper condition of the orbicular ligament. (There is a similar case in the Cambridge Museum in which both humerus and radius are deformed, the neck of the latter being longer than it should be, thus causing difficulty in flexing the forearm.)

In a further discussion of these cases Abbott says that in all the deformity was first noticed when the child began to use its hands, and in no member of the family was any other deformity present. This tendency has twice been transmitted by males, twice by females, while in only one instance has the person transmitting it been herself the subject of the lesion. In one case it has occurred in the third generation, both father and grandfather transmitting the tendency without being affected, and the affection of the grandfather's brother pointing to the deformity having existed one generation earlier still. Abbott states that among cases of congenital dislocation of the radius that have been previously described he has been able to find but one in which the deformity was hereditary. This was the case of Pye-Smith.[16]

It is plain that only those cases can be accepted which (*a*) have been observed by a physician directly after birth, or (*b*) which are hereditary, or (*c*) which coexist with other deformities. If this test be applied it throws out such cases as that of Bessel-Hagen.

Herskovits[18] deduces as hypotheses to explain these luxations: 1. External injuries to the belly of the mother (Cruveilhier) or muscular activity of the fetus (Chaussier). 2. Disease of the capsule or the ligaments (Sedillot), hydrops or fungus (Parise, V. Ammon). 3. Disease in the central nervous system, with consecutive contractures (Guerin) or muscular paralysis (Verneuil). 4. Peculiar fixation of the limbs *in utero* (Dupuytren). 5. Defective construction of the joint (Paletta, Breschet, V. Ammon).

Appraillé[24] has written an exhaustive monograph on congenital malformations of the upper extremity of the radius. His cases are of congenital absence or defective development of the bone rather than of dislocation. From the functional point of view, however, they also are characterized especially by absence of the movements of pronation and supination of the forearm. He believes them to be the result of quite extensive amniotic compression occurring before the formation of the skeleton.

DISCUSSION.

Dr. John T. Bottomley, Boston—My personal experience with congenital deformities of the radius has been absolutely *nil*. I have here two reports of cases from Dr. F. J. Cotton of the out-patient department of the Boston City Hospital, which I will read. The luxations were similar, though not congenital:

Case 1.—*Syphilis of the elbow, congenital.*—M. R., aged 15, doubtful specific history. Three years ago trouble in the left elbow. She was first seen two years ago, at which time there was backward luxation of the radius, bony cartilaginous masses at the lower end of humerus, the radial head and the ulna. There was much loss of motion, especially of supination, of which there was none. There was not much pain and no spasm. Operation refused. She was treated with potassium iodid for two or three months and then lost sight of. About a month ago she was looked up, and I found the motion slightly improved, but the masses are unchanged.

Case 2.—B. H., aged 17. For two years she has had trouble with the elbow, which has not been painful, but has caused much limitation of motion. Congenital specific history. At the present time is under treatment for iritis. Her condition was almost exactly like Case 1, but with dislocation of the radii at both elbows. She was operated on in December last, at which time there was excision of the heads of both radii with transplantation of the distorted orbicular ligament to original site. Early mobilization followed, and she was treated with potassium iodid. Ether was administered once in order to free adhesions. Excellent results followed, and all motions are now practically normal on one side; much improved and still improving on the other side, but supination is not free. Both cases were what is described as false tumor albus. The radial luxation results from the thrust of the raw cartilaginous formation. There is no synovial disease.

Dr. Fred. B. Lund, Boston—I have seen the cases reported by Dr. Cotton, and the result he has obtained in one arm is certainly remarkable. The motion is not perfect, but it is a material improvement, and it is certainly a revelation to see what that operation has done.

Dr. De Forest Willard, Philadelphia—I have seen two or three cases of congenital dislocation of the head of the radius and a number of cases where there have been various congenital defects of this region. When the humerus or the radius are affected the hand is usually carried in the position of extreme pronation. I do not think that any law can be laid down in regard to operation in these cases; every case must be studied according to the conditions presented, and from the standpoint of the type of distortion. In a case presenting the symptoms described by Dr. Powers, the chances are decidedly in favor of a gain by excision of the radius, together with section of the muscles to relieve the extreme pronation. In congenital and birth palsies from injury of the brachial plexus we nearly always have this same pronation. It may be relieved by cutting off the flexor and pronator muscles from their attachment to the humerus and ulna. The arm can subsequently be used 5, 10 or 15 per cent. better, while the improvement in the appearance is 30 to 40 per cent.

Dr. Charles A. Powers, Denver—One's first thought in such a case as this would be to take out the head of the radius. The parents refused to have this done unless given positive assurance that definite benefit would result. In view of the associated conditions and after a careful study of the literature on the subject I did not feel that I could give them this assurance. I believe that Willard's suggestion of dividing the internal rotators of the humerus to be a very useful one. I should be obliged to carefully study the histories of the cases cited by Dr. Bottomley before being certain that they were analogous to the one which I present.

Reasons for Joining the Medical Association.—To be identified with the county, state and national organizations, just as every patriotic citizen exercises his rights of suffrage in local, state and national affairs. To assist in raising the political and social standing of the profession to a higher plane. To show interest in all matters medical which should demand the attention of any legislative body. To assist in demonstrating that the medical profession is not less noble to-day than hitherto; that its members have not grown so "commercial" as to consider their skill as simply a "stock-in-trade" for sale to the highest bidder, but that love and sympathy for the human race are the prime instigators of their every action. To assist in unifying the opinions of the best professional conduct, and in supporting such a code of ethics that the members may not be constantly harassed by temptations and uncertainties as how to proceed.—*N. Y. State Jour. of Med.*

NECESSITY FOR MORE CARE IN THE TREATMENT OF SKULL FRACTURES.*

W. H. EARLES, M.D.
MILWAUKEE, WIS.

The substance of this paper is based on the following propositions:

1. Fractures of the skull are not always recognized as such until too late to receive proper treatment.

2. Fractures of the skull when not properly treated at or about the time of fracture, occasionally result in death, and if not in death in serious remote consequences.

3. Fractures of the skull, when properly treated, usually terminate satisfactorily.

Every practitioner is aware that a large number of skull depressions, with their usual concomitants, are constantly forcing themselves on our attention. It is, we believe, right to assume that surgeons are familiar with the mischief that such depressions create, and would not knowingly allow them to remain were they recognized at the time of injury. As no special reasons exist for these omissions, we are forced to the conclusion that carelessness at the time of the first examination is responsible for the errors in diagnosis and their consequent evil effects.

The conclusions of Hippocrates—sometimes credited to Sir Astley Cooper—that "No injury to the head is too slight to be despised, nor too severe to be despaired of"—were never clearer than to-day, and still many of us fail in appreciating their significance, or if appreciating, fail to profit by them.

An apparently insignificant scalp wound may be associated with a serious fracture beneath, and even a contusion of the scalp may cover a fracture, with depression and accompanying laceration of brain tissue and coverings. The scalp wounds may be ever so carefully dressed and the subsequent healing be ever so perfect, but unless our range of inquiry is sufficiently comprehensive to take in all possibilities, deeper injuries may remain, to be followed by headache, epilepsy, or even insanity. Usually these cases do not present themselves for examination until the evil effects of injury are fully established and little can be done for their relief.

Roberts tells us in his "Fractures of the Cranium" that their importance and interest center not in the damage done to the bone, but in the associated injuries sustained by the brain and its membranes. He also tells us that the inner table is nearly always more extensively broken than the outer. Keen says that "fractures of the inner table alone can only be suspected." Starr (Brain Surgery, p. 27) reports two cases operated on by McBurney, of which he says: "The pressure of splinters of bone cracked off from the inner table of the skull and imbedded in the brain in the motor area, for the arm with cysts at the same place was demonstrated." Da Costa warns us by writing: "The prognosis of fractures of the vault depends on the extent of brain injury, rather than on the extent of bone injury."

In this connection we must not forget that any injury sufficiently violent to produce a fracture of the skull, is also sufficiently violent to produce injuries to the soft parts beneath. In support of this statement we may be pardoned for submitting the following, taken from the clinical records of the writer: From an analysis of 86 cases where injury to the skull wall existed, 68 were accompanied with probable, and 57 with positive, evidence of cerebral disturbances. These conclusions were verified in 52 cases through operation. Clinical reports of competent observers, coupled with everyday experiences, have clearly demonstrated that blows or falls on the head may cause serious trouble, both present and prospective, without producing fracture to the skull wall. If this be true, how much more likelihood is there of such conditions being present when fracture exists, especially if that fracture be depressed. It is on the effects of these injuries, rather than on the injuries themselves, that we would lay emphasis, and to invite attention to the necessity of a full and correct diagnosis at or about the time of injury, in order that either condition may be properly treated. Every case of recent head injury, however trivial it may appear, should, we believe, be treated with the greatest consideration, lest damage to hidden and important structures escape our attention, thus leaving a foundation for future trouble which too often is irreparable.

What shall we do to improve existing conditions? Make a thorough examination at or about the time of injury if possible, and then rationally treat the conditions found. Open wide the scalp wound, carefully examine the bone beneath, and if this be found injured, then examine the brain. An examination of the tissues suspected of injury when cleanly and carefully made, does not expose the patient to any special dangers, while it may be of the most significant value, by determining conditions and leading to treatment that will result in the prevention of very undesirable consequences. This is a rational surgical procedure based on science and common sense. On this point Otto Schar, in the *Archives of Clinical History,* says: "Epilepsy following injury to the skull can, in the majority of cases, be avoided with almost absolute certainty if only active and proper treatment be instituted at the time of injury." Again we quote from Da Costa when he says: "Trephining cases where no symptoms exist, although there is marked depression, often prevents disastrous consequences arising in the future."

We believe that all fractures of the skull with depression should be trephined, the depressed bones elevated, and underlying soft parts carefully examined, and if found injured, repair attempted.

We believe that all fractures of the skull with or without depression when symptoms of cerebral disturbance exist, should be trephined. We believe that all skull fractures, regardless of the presence or absence of cerebral symptoms, should be carefully examined before the soft parts are closed over them.

In operation in no other part of the body does the surgeon close the wound until he has satisfied himself as well as may be, as to the conditions beneath.

Under ordinary conditions the necessary and proper treatment may be carried out. Thorough cleansing of the parts to be operated on may be secured in almost any room; the operator and assistants must be clean, as must the instruments, sponges and dressings. The scalp is raised, the underlying bone examined, and if fragments are found, they must be removed. A button of bone is then removed with the trephine and the parts beneath examined. If found necessary, the opening is to be enlarged with the chisel. If only the dura be torn, it may be united with catgut; if the brain tissue be injured, any ragged edges must be removed—the freshened edges approximated and so retained with fine sutures—all depressed bone must be elevated, when the scalp may be closed in the usual way with or

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

without gauze drainage as circumstances may seem to warrant.

Every patient to-day, of whatever condition, is entitled to intelligent treatment when injured; every surgeon should be prepared to give this treatment when called on to do so. These statements are especially true when associated with injuries to the head. We should, therefore, aim to be thorough in our work, guided by the clinical experience of the past, to the end that full justice may be done both patient and doctor.

Carelessness in the treatment of the class of cases referred to, appears to be responsible for at least much subsequent suffering, and ought to be discouraged.

Drawing on the clinical experience of the able observers quoted in this paper, as well as from the daily experiences of practitioners generally, we are forced to the conviction that not all that is possible is being accomplished in head surgery. Even were the remote consequences less deplorable than we find them, there would still be sufficient reason for reformation along these lines.

We labor night and day with commendable energy, and write volumes on conditions of the appendix; the midnight lamp finds us devising contrivances for the repair of the intestines; the gall bladder and its ducts command our closest attention—then why make the skull, the storehouse of the most important organ in the body, a matter of secondary consideration?

We all know that any impairment of the brain seriously affects the entire economy. We should also know how when possible to prevent this impairment, for here, as nowhere else, do we recognize the force of the adage, "Prevention is better than cure."

There are a greater number of heads than appendices. By virtue of their exposed anatomic positions they are more frequently in need of repair than are the intestines. When seriously injured, they expose the patient to greater dangers than do gallstones.

Why not give them that consideration their importance entitles them to?

DISCUSSION.

DR. J. GARLAND SHERRILL, Louisville—This subject is one of great importance to all men who are doing surgery, especially cranial surgery, and I believe that many cases of this class are not treated properly as mentioned by the speaker. This occurs for many reasons, and a very important one is, that the diagnosis is not made, and we can only say that diagnosis of fracture with trouble within the cranium is not always easily made. I believe that the old classification of symptoms is largely responsible for this condition. It is possible to have grave lesions of the brain with but slight symptoms, and sometimes with extensive damage to the brain the patient will be able to be up and about, the symptoms coming later. If we have the symptoms of compression of the brain, then we have a demand for an operation, but there is no less a demand for operative procedure where the symptoms indicate what has been formally known as concussion of the brain. I believe when you make a diagnosis of concussion of the brain you should always make a thorough examination of the shaven scalp. Localized pain on pressure is of the greatest importance in making your diagnosis. In connection with this symptom the use of the percussion hammer or your finger will often elicit a crack in the skull, which you would not otherwise be able to discover. In connection with these symptoms you should watch the pulse, respiration and pupillary reaction; these are quite important. In these cases the temperature rises as the blood flows at the base of the brain and the pupil becomes dilated and fixed.

In concussion of the brain you often meet another symptom, a rapid irritable pulse, while the pupil is not fixed and dilated as in compression of the brain. Taking these things into consideration a diagnosis of trouble within the skull can be made, and when this fact has been established I believe that most of the fractures of the skull should be investigated, except those very serious fractures of the base of the skull where there is very little hope for relief, but I believe that the field for operative procedure will be widened, even in these cases. All depressed fractures of the skull and all compound fractures should be trephined, and even linear fractures, especially when brain symptoms are present.

DR. CARL WAGNER, Chicago—In connection with Dr. Earles' very suggestive paper I would like to report two cases which tend to illustrate the imperative necessity of operating on all cases of depressed fracture of the skull. Of these two, the first one represents the one extreme, where the injury appears to be so slight that it hardly seems worthy of attention, or even escapes notice, while the second typifies the other extreme in which the case is seemingly utterly hopeless and beyond human aid.

In the first case the mother called me on account of an eruption of the skin, which she took for scarlet fever. The skin eruption did not resemble that of scarlet fever or measles, neither were any throat symptoms present. Temperature 102. The child had had several attacks of convulsions, and on being put on the floor described semi-circles to the right and then fell, insteading of walking in a straight line. This attracted my attention to the brain, and examination of the head I found a sensitive little spot and a small crust covering a slight abrasion of the scalp.

The mother then seemed to remember that the child had fallen against the sharp edge of the leg of the bed about two weeks previously. The child had not complained at all at that time. On operating, a stellate fracture with depression of the bone and pus between bone and scalp, as well as oozing through between the bone splinters from underneath, was disclosed. Another abscess was found directly under the dura mater, containing about a half-teaspoonful of pus. Immediately after the operation the temperature became normal and the child recovered quickly. This case was presented to the North Chicago Medical Society three years after the operation, where I could show that the whole defect of the bone had been closed up by new osseus tissue.

The second case, a boy of 7, fell from the third story on a stone pavement, head first. Dr. Williams and Dr. H. Wagner, who had been attending the boy during the two hours since the accident, informed me that the child had been lying absolutely motionless, with knees and arms flexed, with stertorous Cheyne-Stokes respiration, during the entire time, almost pulseless, the pupils dilated and fixed and did not respond to the effect of light. There was a profuse hemorrhage from the right ear, both nostrils and mouth. On top of the right side of the head near the frontal region of the skull a deep depression large enough to admit three fingers could be seen.

I made an extensive Lannelongue incision, without anesthetic. The injured field was exposed. The anterior and posterior branches of middle meningeal arteries were tied, the ruptured longitudinal sinus tamponed, the lateral sinus on the right side blocked with gauze. The bony defect was very nearly as large as the palm of the hand. A bi-parietal fracture, which had torn the longitudinal sinus, extended through the temporal bone, which was afterwards verified by the examination of the ear, where Dr. Gradle found a scar in the drum and bone. The boy left the hospital fourteen days after in good health and has been for the last seven years a good, bright scholar in school.

DR. T. J. SULLIVAN, Chicago—Cases of fracture of the skull may be divided into two classes: simple and compound. The simple cases are cases to be placed under observation, and when the conditions warrant interference by surgical intervention. The compound fractures, of course, should always receive all the relief that is afforded by modern surgery, and the wound should be dressed with a primary antiseptic dressing at the time of the traumatism, so that when the patient is received by the surgeon the case from the time of the injury to the time of the operation is controlled by primary antiseptic dressing. The best antiseptic is bichlorid of mercury, in a strength

of 1 to 1000. All the compound fractures certainly require surgical intervention. In these cases the operation should be proceeded with with all surgical precaution in the way of elevating the fracture and restoring the condition of the patient. In cases where the meningeal vessels are torn, and where it is very difficult to do the operation without hemorrhages, we can safely place a quantity of the normal salt solution within the dura. In some of those cases we have very severe hemorrhage from the meningeal arteries, and good may be derived from the little device referred to. The Mosaic may be secured to the dura by careful adjustment with a very fine through-and-through catgut suture. In this way we can control the hemorrhage, and after about forty-eight hours we can reduce the Mosaic and insert packing, which may be done at once in those cases, where hemorrhage is not an important factor. In that way we provide against the danger of adhesions of the dura and the scalp. Later in those cases in which that procedure has not been carried out and we have adhesions between the dura and the scalp, we have a very beautiful little procedure that we can resort to. By making a large flap and dissecting it off carefully and then by running the chisel in between the parts, we can keep the dura separated from the scalp and provide against adhesions. Of course, five minutes is too short a time to systematically dissect these parts. It seems to me that all classes of injury to the skull can be divided into two classes, simple and compound, and all cases of simple fracture should be kept under observation and surgical interference undertaken as soon as the motor symptoms are noticed. The compound fractures demand immediate operation under the most thorough aseptic methods. When sepsis does occur, a median incision should be made in the skull and drainage provided. At least in one instance of compound fracture of the skull, which had gone over for eighteen months after the time of the injury, it was possible to save the patient by those great multiple incisions. In this case the temperature had run up very high, the patient had had convulsions, but was relieved by this operation.

DR. B. B. DAVIS, Omaha, Neb.—When I see a case of head injury I always try to keep this point in mind. It does not matter how much the fracture or how small the fracture is, or how much injury there is to the membrane or to the bone, the point that we are concerned with more than anything else is the extent of the injury to the brain. I have been very much surprised in some instances to see quite an extensive fracture of the bone, with practically no injury to the dura or to the brain, and, on the other hand, I have seen cases where the fracture was insignificant, and have found a great deal of injury to the dura and perhaps to the gray matter of the brain. To decide when to do an operation immediately and when not to do an operation is not always so easy, and I think we should always consider, first, is there any danger if we do not do the operation, and second, are we going to leave this patient in a bad condition if we do not do it? I think we have trephined in two or three instances unnecessarily. In some cases I have not found enough pathology to warrant the operation. The question is whether there is not enough cicatricial tissue to form dural adhesions, so that in the future that patient may have paralysis due, not to the original injury, but to the trephining. I think we should not do this operation unless it is absolutely necessary.

DR. G. S. BROWN, Birmingham, Ala.—I merely wish to report a case of injury to the middle meningeal artery with resulting paralysis. I merely report it because it is a case of very unusual occurrence, and I never heard of one being reported before. It occurred in my practice about three weeks ago. I operated on it and found a very small clot about the size of a white bean. The convulsions and paralysis and all the other symptoms disappeared two hours after the operation, and in ten days the child was up and well.

DR. CHARLES H. LEMON, Milwaukee, Wis.—In injuries to the skull, especially those caused by a fall from a height, we sometimes find serious intracranial disturbance without demonstrable hemorrhage within the cranial cavity, and I think it is the experience of those who have seen many of these cases that some cases are allowed to die under a diagnosis of concussion of the brain, which might possibly have been saved if subjected to operative procedure. There is a pathologic condition of the brain following trauma that is oftentimes overlooked. We may have, and we frequently do have, contusion of the brain itself and its membranes, and as the result of that contusion we have edema of the brain causing intracranial pressure of a fatal character which might be avoided by trephining and drainage. We are expecting in the brain a power of resorption that we do not expect in other tissues of the body. We seem to have lost sight of the fact that in the arrest of the fall, when the delicate structure of the brain is contused by its sudden sharp contact with its bony envelope, it must undergo the same pathologic process, with all its attendant inflammatory changes, that other soft tissues similarly injured undergo more favorably situated for the purpose of expansion.

There recently came under my observation the case of a man who fell forty feet, receiving a compound fracture of the right wrist with numerous contusions of the body without apparent injury to the head. Ten days after the injury he developed a partial paralysis of the right arm and right leg and became markedly comatose, the hemiplegia becoming complete on the eleventh day. On the eleventh day his temperature was 102, pulse 145 and respirations 10 per minute. Coma complete. I trephined the skull low down on the left side, opening the middle fossa. There was no extradural hemorrhage and no pulsation of the brain could be seen. The dura was incised. A contused area of the brain bulged into the wound. The center of this area was markedly ecchymotic and the surrounding cortex of the brain appeared infiltrated. A grooved director was inserted which permitted the escape of a large amount of cerebrospinal fluid, relieving the intracranial pressure, and at the end of ten minutes the brain began to pulsate vigorously. The wound was drained by strands of catgut and heavy moist dressings used to favor the relief of tension by drainage. In three days all paralysis had disappeared, the man was able to talk and the temperature dropped to 100 degrees.

I cite this case because it illustrates that in all cases of severe injury to the skull there is likely to be contusion of the brain without hemorrhage followed by inflammatory reaction which may produce fatal intracranial pressure. This may occur without demonstrable signs of injury to the head, so that in order to give these patients every possible chance for recovery the skull should be opened for the purpose of relieving tension and by providing free drainage afford the brain the greatest possible room for expansion.

DR. T. C. WITHERSPOON, St. Louis—I take it for granted that the subject under discussion is injury to the brain following fracture of the skull. There are four sources of danger: First, hemorrhage; second, laceration or more extensive pulpification; third, presence of bone or foreign body in the brain or making pressure on it; fourth, sepsis. The most dangerous form of fracture as far as infection is concerned is of the base of the skull. It is certainly bad practice to irrigate the nasal cavity, as some recommend, to aid in disinfection. The water is too often the conveyor of infection. Above all things, the air of the room should be kept moist to prevent crust formation as far as possible.

As to exploration in case of hemorrhage or laceration, I feel the dura is too often opened. Adhesions are necessarily formed at the cut in the dura, and epilepsy is a possible sequence. These cases suffer from sudden movements or jars. Two cases have come under my observation in which I was sorely tempted to open the dura initially, and time has demonstrated the wisdom of not doing so. About 14 years ago a gentleman was thrown from his horse and suffered a fracture at the base of the skull. A profound coma lasted for a while, which left, on clearing, a distinct hemianopsia. At this time I favored exploration, but he fell to the care of another surgeon and I lost sight of him. Six months ago he returned to me, asking that I explore his brain to find out why he still had the hemianopsia. I advised against this, stating it was too late to accomplish anything regardless of the primary cause. In a short time he

returned with a statement made out by his attorney to the effect that I would be in no way responsible for the outcome in case I operated. With him he brought some friends to urge this on me. On opening the skull we found absolutely nothing in the area of the cuneus. Evidently the original injury was a laceration deep in the basilar area.

The second case was that of a man with fractured skull due to a rock falling on his head from a height. The cutaneous wound was small, but the fracture involved the major portion of the left side of the skull. There was no paralysis, but complete aphasia; neither could he write. His understanding of written language was questionable, likewise that which he heard. The bone just above the commencement of the Sylvian fissure was most depressed. This was removed. The remaining area on the side of the head was left intact after adjusting the fragments of attached bone as best I could. A primary healing followed, and at present he can speak well enough to get about and ask for necessities. The distinct localization made it tempting to explore further in each case, but I am sure it would have been more harmful than beneficial.

Dr. W. H. Earles, Milwaukee, Wis., closing—This paper has been read in the hope that it may stimulate a more thorough application of the knowledge we have on this subject. The point that I especially wish to emphasize is that we do not exercise that amount of care and judgment that we should in these cases. Nowhere else in our operative work are we so tempted to hurry up the operation without satisfying ourselves as to the exact conditions present.

A few years ago I was called to treat a man who was suffering from epilepsy. He gave a history of good health until one year prior to the time that I saw him, when he fractured his skull in jumping from a fourth-story window. He told me that he had a silver plate in his skull. I did not credit the silver plate part of the history, and did an operation on the injured side of the head, when I found this plate (showing plate). His epilepsy, however, continued. I was satisfied that there was some condition present closely associated with his fits, and, after waiting two weeks, I had his head again shaved. On making the second examination I found on the opposite side of the head from that operated on, a very small scar and beneath it a depressed fracture. The scar was so small as to have escaped my attention at the time of the first operation, and the original wound had apparently been so insignificant as to have escaped the notice of the operator at the time of the primary operation. He had seen the injury on one side and performed an operation for its repair, but the injury on the other side being insignificant in appearance, did not receive apparently the attention it deserved. After the second operation the epileptic seizures discontinued, and did not reappear as long as the man was under my observation—about six months. I do not know what the final results were.

I cite this case to show the necessity of great care in examining the class of injuries referred to. I think if we will exercise what knowledge we have, and be more careful in our primary examination of the patients, we will have fewer cases of traumatic epilepsy.

Intoxication with Croton Oil.—The *Bulletin of the Societe de Pharmacie* of Bordeaux gives the details of a criminal case in which a wife killed her husband by adding two or three drops of croton oil twice daily to his food, for five months, with rare exceptions. The symptoms induced were a smarting and burning in the throat and stomach, violent vomiting after meals, daily repeated copious alvine discharges, with intense colicky pains for hours, and death at last in extreme emaciation. The medical experts were unable to detect the croton oil by any know test in the cadaver, even after the wife had confessed, but Barthe was able to identify it in spots on a cloth with which the bottle had been wiped. He also emphasizes the siccative properties of croton oil. The stomach and small intestine showed a number of superficial erosions and hemorrhagic dots, the organs much congested. No characteristic lesions were noted in the large intestine or other organs; the kidney and liver were apparently normal, as also the brain, etc.

CLINICAL DIAGNOSIS OF INTESTINAL PARASITES.*

CHARLES WARDELL STILES, Ph.D.
Chief of Division of Zoology, Hygienic Laboratory, U. S. Public Health and Marine-Hospital Service.
WASHINGTON, D. C.

In diagnosing intestinal parasites, we may use various methods, but the best method is undoubtedly that of a microscopic examination of the feces.

DIAGNOSIS BY SYMPTOMS.

The practitioner who relies on symptoms alone for his diagnosis will undoubtedly often successfully recognize the true nature of the trouble, especially in severe infections. For instance, when we are in the infected area of hookworm disease and meet a typical clay-eater we note a complex of symptoms which is quite characteristic, and in most cases of this kind a microscopic examination seems unnecessary. In numerous medium cases and in practically all light cases of this disease, however, a diagnosis on symptoms alone is uncertain unless we find severe cases, such as clay-eaters, in the same family. Outside of the infected area, probably few physicians would care to risk a definite diagnosis of this disease on symptoms alone even in the severe cases, while in medium and light cases it would be almost folly to do so.

BLOOD COUNTS.

Blood examination has become almost a matter of routine in the better hospitals and also in the private practice of many physicians, and in all such examinations we should bear in mind the important fact that an increased eosinophilia is an indication of possible infection with animal parasites. Hence, when an increased eosinophilia is noticed, we should immediately make a microscopic examination of the feces for eggs or embryos of parasites, and if these are not found we should consider the possibility of trichinosis, especially in obscure typhoid-like cases.

GROSS EXAMINATION OF THE FECES.

Physicians in general appreciate the importance of a gross examination of the feces of infants, but less attention is given to an examination of the stools of adults.

In some cases a gross examination of the stool will reveal segments of a tapeworm, or in some cases of nematode infection the adult worms may be found. This, it seems, is more likely to occur after a patient has taken calomel or a small dose of some anthelmintic or after food has been withheld for twenty-four to forty-eight hours. In the first stage of trichinosis, especially where the diarrhea is severe, as in children, the adult trichinæ may sometimes be found. In hunting for these trichinæ the stools should be diluted with warm water and examined in a flat glass dish held over a black background.

The color of the stools is occasionally suggestive in case of infection with blood-sucking parasites, such as hookworms. The hookworm stool (such as usually seen in very severe cases) is reddish brown in color.

BLOTTING PAPER TEST.

In hookworm infections a very simple test may be made with blotting paper or even with an ordinary newspaper. Several ounces of the stool should be wrapped up in paper and allowed to stand for a few hours. In severe cases and in many median cases it will be noticed

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

that a distinct reddish-brown stain is formed on the paper. In this test, however, there is an error of 30 per cent. or more.

Odor and Litmus Test.—While the odor of feces from parasitic infections is sometimes offensive, I have not been able to discover anything sufficiently characteristic about it to attract special attention. The litmus paper test is of no value, so far as my observations go.

MICROSCOPIC EXAMINATION OF FECES.

I believe that a routine microscopic examination of feces should be made in all hospital cases and also in all private cases so far as practical. The results which the Zoological Division of the Hygienic Laboratory has recently obtained in examining the patients at the Government Hospital for the Insane amply demonstrated the value of such work, for we found that 3 per cent. of the first 500 cases examined showed hookworm infection.

There seems to be an impression that fecal examination involves very disagreeable work. While it must be admitted that some stools are offensive, I would personally much prefer to make a feces examination than a sputum examination, for in working with feces one is much less likely to experience that nauseating sensation so commonly resulting from an examination of sputa.

TECHNIC.

The technic involved is exceedingly simple, since it is not necessary to stain the preparation. A portion of the feces, say 1 to 5 grams, is taken from the stool, wrapped up in a piece of paper and taken to the laboratory. Or, if it is desired to test for protozoa as well as for worms, it is better to place the specimen in a bottle so that the material will not dry. To avoid errors in interpretation it is well to make the examination as promptly as possible, although an experienced operator may examine the specimen even if it is a week or so old. In examining old specimens, however, it must be recalled that the older the specimen the more likely one is to fail to recognize protozoan infections.

An elaborate series of instruments may be used in preparing the slides if desired, or, if instruments are not at hand, a match will suffice.

For slides I prefer the large 2 by 3-inch, such as are used for large sections or for trichina inspection, rather than the 1 by 3-inch slide generally used in bacteriologic work. These larger slides are much more easily handled than are the smaller sizes. Having thoroughly cleaned the slide in order to remove any eggs which may have clung to it from some former examination, a drop of water is placed on it; next take a minute portion of feces on the end of a match or a glass rod and thoroughly mix it with the water so that the resulting mixture is not too thick; add more water if necessary. Next cover the mixture with a cover glass (square cover glass preferred) and the preparation is ready for examination. As many as two to four cover glasses may be conveniently placed on one slide and at least ten cover-glass preparations should be examined before a negative opinion is given.

In the work several very simple precautions are to be observed, namely, the specimen and the preparations are to be kept protected from flies, the hands are to be immediately cleaned if accidentally soiled with the feces, especially if nothing is known regarding the condition of the patient, and all glassware is to be thoroughly cleaned (hot water or hot water and soap). In case of the presence of *Tænia solium* in man, double precautions are to be observed, as the egg is infectious for man. In case of examining feces from dogs, the possibility of the presence of *Tænia echinococcus* and its transmissibility to man should be held in mind.

The biologic principle on which fecal examination rests is that the eggs of different animals are more or less characteristic. Accordingly, to properly carry out the examination one must become familiar with the eggs and embryos of different species, also with the form of certain plant cells and fibers which might be mistaken by the uninitiated for eggs or embryos of parasitic worms.

Not every egg found in the feces indicates an infection of the intestinal tract. In the case of infection with liverflukes, for instance, the eggs are discharged in the stools, and some of these forms resemble more or less closely the eggs of certain intestinal parasites. In lungfluke infection the eggs of *Paragonimus* may be found both in the sputum and in the feces. In bloodfluke infection the eggs of *Schistosoma* may be found both in the feces and in the urine. In certain cases, therefore, it is necessary to examine either the sputum or the urine in addition to the examination of the feces.

For illustrations of the eggs most commonly found, I refer you to any work on clinical diagnosis or to Bulletin 10, Hygienic Laboratory, U. S. Public Health and Marine-Hospital Service.

A CONTRIBUTION TO THE STUDY OF THE SUMMER DIARRHEAS OF INFANCY.*

J. H. MASON KNOX, JR., PH.D., M.D.,

Assistant in Pediatrics, The Johns Hopkins Medical School; Physician in Charge of the Thomas Wilson Sanitarium, Mount Wilson, Md.

BALTIMORE.

It is with great hesitancy that any attempt is made in this paper to enter a field that has been so thoroughly investigated during recent years as that embraced in the title of "The Summer Diarrheas of Infancy." The zeal with which these intestinal disorders of children have been studied lately is in direct ratio with their neglect by early medical writers. Although, as Dr. Booker[1] has shown, there are occasional references among the ancients to diarrheal troubles in infants in the summer months, there is no clear history of these diseases prior to their appearance among the colonists in this country. As he suggests, the importance of human life in this newly-settled land may have called sharp attention to a malady which was each summer carrying away the children of the settlers in large numbers. The malady, called the "dread of parents and the opprobrium of physicians," was thought at first peculiar to America. The yearly outbreaks in the larger towns scattered along the Atlantic coast were recognized and described under various names by local physicians, but the first adequate description of these maladies seems to have been made in 1773 by Dr. Benjamin Rush.

Knowledge of these disorders spread gradually in this country and in Europe, and it was not until the early part of the last century that their great importance was recognized. As is the case with other diseases, the clinical descriptions of many of these early observers leave but little to be added by their successors. They ascribed the causes of the disorders to various conditions, some of which will pass muster to-day, to the character of the atmosphere, cold, moist or hot, to direful miasms, to overcrowding, to improper food, to teething, to faulty

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

action of the liver, and so on. They recognized the epidemic character of the disease and the lines of treatment adopted were in the main those now followed. Food was restricted, prompt purgation resorted to, opium was used in moderation, and the advantage of removing the little patients from crowded districts to the country was recognized. With the advent of the science of bacteriology, new zest has been added to the study of these complaints. Then, for the first time, there seemed possible a rational explanation of the infectious nature of the affection. The intestinal tract of the healthy infant was found to swarm with bacteria of many varieties.

It would be needless to even mention the host of workers in this field, or the names of the numerous bacterial forms isolated. Perhaps the most authoritative work on the subject has been done by Escherich of Vienna, formerly of Gratz, who noted the predominance of *B. lactis aerogenes* in the upper bowel of the infant, and of *B. coli communis* in the large intestine, during health. In diseased conditions the differences between the flora in the upper and lower bowels are less marked. In addition to other varieties found in the intestinal tract, including the interesting *B. acidofilus* of Moro and Finkelstein, several forms known to be pathogenic for man have been isolated from the stools of infants suffering from diarrhea. Thus, among others, the pathogenic cocci, *B. proteus vulgaris, B. pyocyaneus* and virulent forms of the colon bacillus have been described. No single pathogenic organism, however, has been found constantly in these diarrheal conditions, and the conclusions of Dr. Booker[2] perhaps voice the present position of the profession, that "No single organism is found to be the specific exciter of the summer diarrheas of infants."

Notwithstanding these comparatively negative findings, it is believed that there is clinical evidence in favor of the specific nature of these affections. The epidemic character of the disease in our crowded cities during the summer months, its occasional propagation in hospitals and asylums from patient to patient, and the nature of the illness itself, all suggest that the exciting cause of the disorder is an infectious agent not normally present in the body. The factors predisposing to this infection have long been recognized, and experience only tends to emphasize their importance. Thus the disease is much more prevalent among infants of weakened constitutions living amid unhygienic surroundings and nourished by insufficient or improper food. The high temperature during our summer months provides most favorable conditions for the rapid proliferation of bacteria in food products, especially in milk, and the large residue of undigested milk which remains in the infant's intestinal tract as a result of immoderate feeding, or of a weakened absorptive power, forms an ideal pabulum for the growth of bacteria and the formation of deleterious products. So frequently are these conditions incident to an attack of summer diarrhea that many, including Czerny of Breslau, consider improper feeding the more important factor in its production, and the infective element to be of comparatively less moment. Certain it is that the mortality in intestinal diseases of infants is directly influenced by the resistance of the patient, which is in turn dependent upon the condition of the digestive apparatus.

The effort to isolate a single organism which could be shown to be the cause of a large group of these cases of summer diarrhea, has been unsuccessful, because of the difficulty in the separation of such an organism, if present, from the great numbers of bacteria in the intestinal contents. Last summer in the laboratory of the Thomas Wilson Sanitarium,[3] assisted by a grant from the Rockefeller Institute, two investigators, C. W. Duval and V. H. Bassett, succeeded in isolating *B. dysenteriæ* (Shiga) from the stools of forty-two infants suffering with diarrhea. The importance of this finding is evident, as it brings a series of diarrheal cases in young children into relationship with an organism that is the proven exciting cause of certain varieties of severe intestinal disease in adults. It is unnecessary to do more than refer to the history of the organism. It will be remembered that it was first isolated by Shiga[4] in Japan, in 1897, from the stools of patients suffering from epidemic dysentery. In 1900 Flexner[5] discovered the same organism to be the cause of many cases of epidemic dysentery among our soldiers in the Philippines. Soon after Kruse,[6] in Germany, found the same bacillus in the dejecta of patients suffering from so-called "asylum dysentery." It has since been successfully isolated by Vetter and Duval[7] in epidemics of dysentery in this country, and has also been found in diarrheal cases in China, in Constantinople, and in several other sections of Europe.[8]

At the Thomas Wilson Sanitarium the stools of about fifty-three patients, most of them under 1 year of age, were examined bacteriologically, and from forty-two the dysentery bacillus was isolated. Early in the summer those cases were selected in which the stools contained considerable mucus and blood. These were regarded as especially "favorable," that is, that from them the organism could be obtained in largest numbers. Later the stools of twenty-five consecutive infants were carefully plated, and in nineteen instances *B. dysenteriæ* was found. All these babies exhibited some form of intestinal disorder, but the stools of many of the series were largely fecal, and in these cases the organism was present in comparatively small numbers, and was more difficult to isolate. The importance of determining the presence or absence of the bacillus in normal stools was recognized, and the discharges of twenty-five babies, ranging in age from 7 weeks to 2 years, suffering from no intestinal derangement, were subjected to painstaking examination. In none of these cases was the Shiga bacillus found.

A detailed account of the methods employed in isolating the organism will shortly appear,[9] and will be only briefly referred to here. The technic was essentially that used by Dr. Flexner in the Philippines, though several important modifications employed first by Vetter and Duval[7] in their work on adult dysentery, were of great assistance. The stool of the infant to be investigated was collected on sterile gauze and taken immediately after passage to the laboratory. Numerous plate cultures in acid agar-agar were made, choosing for plating, when possible, bloody or muco-purulent portions. After incubation for twenty-four hours, the superficial colonies were marked off and the plates again placed in the thermostat for twenty-four hours, when the new superficial colonies were carefully examined. Duval and Vetter found in their studies that the dysentery bacilli grow out on plates less rapidly than do colon organisms, and that by thus marking the plates one is enabled to select for study the colonies developing more slowly, and thus the ubiquitous colon bacillus could be avoided. The colonies which seemed morphologically favorable after this second incubation were transplanted to glucose agar and all gas-forming organisms discarded. The non-gas-forming bacilli were studied culturally on the various media, and their agglutination reaction tested with serum from the same patient, the sera from numerous other patients,

and with antidysenteric serum furnished through the kindness of Dr. Gay. This agglutinating action of the blood serum for the specific organism was a great assistance in the successful isolation, as it proved to be to Shiga and Flexner, and to all subsequent investigators. The technic of making this test with the dysentery bacillus requires more than usual skill, and thus far wider variations in the amount of agglutinin in the sera from various patients seem to pertain than is the case in typhoid fever. Our experience would indicate that in nearly all cases the serum has some definite agglutinating power for the specific organism if the two are brought together under the most favorable conditions. The serum from immunized horses in dilutions from 1-100 to 1-1,000, agglutinated the organisms isolated from all our forty-two cases, as well as various strains of the dysentery bacillus sent from abroad, while it was quite inert in low dilutions against the typhoid bacillus. Moreover, the blood of our patients agglutinated the organisms isolated at the sanitarium, as well as those obtained from cases of epidemic dysentery in Japan, the Philippines, Germany and in this country, in dilutions varying from 1-16, the least active, to 1-1,000, when cultures of typhoid or colon bacilli tested synchronously were negative. The agglutination reactions were made in drop slides and observed under the microscope. Lenz,[10] in the last few months, has advocated the macroscopic test-tube reaction as being more reliable, and since last summer this method has been used in testing many of our isolations. With some minor differences, the two methods seem to fairly correspond. It is difficult at present to explain many apparent irregularities in the agglutination reaction with the dysentery bacillus, and much further study is necessary before hard and fast lines can be drawn as to the time in which a reaction must take place to be considered positive, and also as to the minimum dilution of the serum to be allowed. These steps toward a recognized technic were gradually taken in the study of the Widal reaction with the typhoid bacillus. However, the Shiga bacillus seems to present more differences in the importance and rapidity with which the various isolations clump than does the typhoid bacillus. In no instance during the summer did normal blood agglutinate any of the dysentery bacilli.

It is too early yet to speak positively of the clinical value of the agglutination reaction. Of thirteen cases tested during the first week of illness, ten gave positive, and three negative, reactions. One case reacted on the second day. Usually, however, reaction was more marked later in the disease. In the chronic cases the blood may remain positive for weeks or months. It is in cases of this nature that the blood tests may prove useful. By this means in a number of our series presenting the symptoms of chronic intestinal disorder, a diagnosis was made on the basis of a positive blood reaction, and a dysentery bacillus afterward isolated from the stools. In several tested cases where the bacteriologic examination of the stools was not possible or convenient, a diagnosis was ventured because of an undoubted agglutinating reaction. It is hoped that when its limitations are understood this blood reaction will prove of assistance to the clinician.

The studies conducted by Duval and Bassett have resulted in establishing the fact that there was present in the intestinal tract of a large number of infants suffering from diarrheal disorders, a bacillus identical with the *B. dysenteriæ* (Shiga), hitherto associated only with the dysentery of adults. They have found also that this organism was pathogenic for animals; that it was present in largest numbers in the deeper layers of the intestine, as shown by scraping the mucosa at autopsy; and that the number of bacilli in the stools was in proportion to the acuteness and severity of the symptoms. The organisms isolated were agglutinated by antidysenteric serum and by the blood of infected patients, never by the blood of those ill with other diseases. They were unable to find the Shiga bacillus in the discharges of healthy infants. In short, the evidence presented by Shiga, Flexner and others, to establish the etiology of dysentery in adults is at hand to show that the dysentery bacillus is also the causal factor in certain diarrheal diseases among children.

It now remains to consider the clinical aspect of this series of cases in order to determine, if possible, whether they belong to an isolated group, or whether they represent in symptomatology and pathology the maladies called by the descriptive epithet, "The Summer Diarrheas of Infants."

TIME OF ADMISSION.

The 42 cases of our series were admitted to the sanitarium between June 13 and August 21 of last summer, 12 being received in June, 25 in July and 5 in August.

AGE.

The age of the little patients varied between 7 weeks and 4 years. The majority of them were under 1 year of age. They may be arranged according to age in the following periods of six months each:

Under 6 months	13
Between 6 months and 12 months	17
Between 12 months and 18 months	8
Between 18 months and 24 months	3
Over 2 years	1

The interest of this classification is that our patients, in regard to their ages, correspond closely to a period in infancy long known to be most susceptible to summer diarrhea.

SEX AND RACE.

The cases were about equally divided between the sexes. But two colored infants are included in our series, as the accommodations for these patients are limited.

HISTORY OF ILLNESS.

Unfortunately, because of the distance of the sanitarium from the city, the patients usually came under our observation after their initial symptoms. The mothers, as a rule, however, gave us a fairly definite history of onset, the record often being that the baby, after a day or two of languor, was suddenly seized with diarrhea, usually preceded or followed by vomiting. At the same time a rise in temperature was noted. Subsequently there was increased constitutional disturbance indicated by a loss of appetite, malaise and restlessness. The stools at onset, although increased in number and often fluid in consistency, were fecal in character. Soon, however, except in the very mild attacks, the fecal odor and appearance were lost, and the discharges were composed largely of greenish mucus, and not infrequently tinged with blood. During the height of the illness the temperature usually continued elevated, and nausea and vomiting, even after a reduced diet, were common. It was at this period that the Shiga bacilli were obtained in large numbers in the stools. These acute attacks varied greatly in severity. In some cases the constitutional disturbance was slight and the stools were little affected; on the other hand, several of our patients presented early symptoms of profound intoxication, evinced by convulsive spasms, excessive nausea and vomiting, and increased languor, ending in coma. A large number of the

cases, however, exhibited quite a different picture After an acute onset, instead of toxemia ending fatally or in a prompt convalescence, the baby showed symptoms indicating a more localized affection of the intestine. In these instances, which included more than half of our series, after variable periods the stools became mucopurulent, and contained often an increased amount of blood, some of it bright red in color. The temperature showed a daily, usually an evening, rise. The appetite remained poor, and vomiting was not infrequent. There was evidence of considerable pain in the lower abdomen; tenesmus was marked. These cases often became chronic and lasted for weeks. They were more numerous during the latter part of the summer, and were less amenable to treatment. Often, despite many carefully prepared diets, there was progressive loss of weight, increase in anemia, and a fatal termination from exhaustion. In several instances in our series the specific infection was superimposed on infants which for months had been suffering from malnutrition and chronic intestinal indigestion. Of several of the clinical features a few words may be added.

TEMPERATURE.

The temperature in the series of cases varied from 95 F. to 105 F. As has been mentioned, daily rises in temperature were often noted. The degree of bodily heat was of clinical assistance only when considered with other signs and symptoms, as a drop to normal or subnormal temperature not infrequently was an indication of collapse, and the illness of several of our patients manifesting constitutional disturbances, ran an almost afebrile course.

GASTROINTESTINAL PAIN.

Gastrocolic was rarely noticed while at the sanitarium, but was present, according to the description of the mother, in a few cases at onset. A large number of the cases of long duration exhibited rectal tenesmus.

NUMBER AND CHARACTER OF THE STOOLS.

The stools varied in number from one to thirty in twenty-four hours. They usually became most frequent in the first three days after onset. The discharges presented also wide differences in character. Some were distinctly fecal, but semi-fluid or fluid in consistency. In the cases showing symptoms of indigestion, the stools were often pasty in character and gray in color. Hard masses would alternate with softer material. The element that was almost constantly present was mucus, either as a firm, translucent, gelatinous substance, or as more fluid, viscid, or stringy material, usually greenish in color. Marked inflammatory lesions of the lower bowel were indicated by the muco-purulent or purulent character of the stool. The amount of blood passed varied from a slight tinge or fleck to dark brown or bright red masses in fairly large quantities. Under the microscope many epithelial cells, varying in number of white and red corpuscles, bacteria, mucous strands and undigested food residue, fat globules and casein, composed the more constant elements.

COMPLICATIONS.

Complications early in the course of the illness were comparatively infrequent. Death in several instances was preceded by the appearance of livid erythematous blotches over various parts of the body. Terminal bronchopneumonia was not uncommon. In two instances there was concurrent lobar pneumonia, and in two other cases acute parenchymatous nephritis developed. Occasional edema of the extremities was noticed not associated with alterations of the kidneys, and in several instances stiffness of the neck and extremities would have suggested meningitis had it not passed away after a few hours.

ILLUSTRATIVE CASES.

A résumé of each of the histories of our series would hardly be profitable, as in the main they present very similar and familiar features. From a large number, however, several may be selected as representing the more important clinical groups. The following is an instance of a mild form of diarrhea:

CASE 1.—A child 18 months old, fed at the table, became cross and irritable. A few days afterward its stools increased to from seven to ten a day and were described by the mother as "green and slimy." On admission to the sanitarium they were found to consist largely of green mucus, with numerous soft, white lumps. They never contained any blood. There was occasional vomiting. Physical examination, negative. There was no marked prostration. On a regulated diet the discharges became homogeneous in form, the mucus disappeared, and the child soon completely recovered.

A much severer type of an acute case with complication is illustrated by the following instance:

CASE 2.—An infant 8 months old, fed on condensed milk and previously well, was suddenly seized with moderate diarrhea. For several days the stools were not more than six in twenty-four hours, but on the day before admission they increased to twenty, and were fluid, with considerable mucus, but no blood. The general condition of the baby became markedly worse. He was feverish, restless and had several fainting spells. On admission the child was in collapse. The rectal temperature was 105 F., pulse 180, face pale, and extremities cold. The eyes were sunken and the abdomen scaphoid. Physical examination of the chest, negative. There was some response to stimulation, and for two days his condition improved. On the third day, however, albumin in large quantities appeared in the urine, with many granular casts and pus cells. The tissues about the neck and chest became edematous; the child gradually became more listless; coma ensued, ending in death three days after the renal involvement. At autopsy the intestines were little altered. There was no distension. The mucosa was pale. Peyer's patches were moderately enlarged and somewhat injected, as were also the solitary follicles. The mesenteric glands, particularly those draining the sigmoid flexure and rectum, were somewhat enlarged. There was no lesion of the intestinal mucosa. The kidneys were the large and white kidneys, indicating acute parenchymatous nephritis.

In the next case, although not unlike clinically, there was evidence of a destructive lesion of the lower bowel.

CASE 3.—An infant of 5 months, fed for four months on condensed milk, began two weeks before admission to be fretful and to vomit occasionally. Soon after the stools increased in frequency and were described as "yellowish and slimy." No blood was noticed. The child was found, on examination, to be rickety and anemic, and did not improve after admission. There was a moderate fever. The stools were six to seven a day, and consisted of thick, viscid mucus and contained considerable blood and pus. There was some rectal tenesmus. The baby gradually lost weight and strength, the blood in the stools increased, and death ensued about five weeks after the onset of acute symptoms. At autopsy numerous small hemorrhages were found scattered through the ileum; the mucosa of the entire colon was thickened and covered with bloody mucus; the solitary follicles were much enlarged and the seat of numerous small ulcerations. The mesenteric glands were everywhere swollen and red.

One other history will be cited as illustrative of a case of long-standing malnutrition.

CASE 4.—An infant was 7½ months of age, a twin and delicate from birth, breast-fed for two months, but during the remaining five months the diet has been variously modified. For most of this time the stools varied from two to eight in

twenty-four hours and frequently contained mucus. There was little or no gain in weight. Frequent colic; occasional vomiting. The abdomen was usually distended. Two weeks before admission these symptoms became somewhat aggravated. The child was found on examination to be markedly rickety, with general glandular enlargement. After admission its general condition remained about the same. For days at a time the stools would become more homogeneous and firm, only to show a return of mucus and pus after a short period, despite careful feeding and rectal irrigations. There was never any blood. The temperature was but slightly elevated. The infant remained with us until the end of the season, and was discharged unimproved.

What has been said of the clinical history of our forty-two patients and the illustrative cases cited, are sufficient, certainly, to warrant the assertion that, so far as can be told at the bedside and in the autopsy room, we were dealing last summer with no unusual form of intestinal disease, but with the common varieties of summer diarrhea. Our cases fall naturally into two or three large groups which have long been recognized, namely: into those of an acute dyspeptic or fomental diarrhea (gastrointestinal catarrh) of varying degrees of severity, in which the toxic symptoms were prominent—twelve cases; into those of colitis, marked by the definite inflammatory lesions of the intestinal mucosa—twenty-six cases; and again into at least four instances which were primarily malnutrition, marasmus, or chronic indigestion, but in addition to which the element of infection has been added. It is well understood that these divisions of intestinal diseases do not represent definite clinical entities, but that one form of illness may readily pass into another; that the cases of ileocolitis usually begin with symptoms of dyspeptic diarrhea, and that ill-nourished infants are particularly prone to either form of disorder. Of the most fulminating variety of the toxic intestinal diseases, namely, cholera infantum, we had no example in our series. It is suggestive, however, that in the stool of an especially acute case, one thought at first to be cholera infantum by the attending physician, the Shiga bacilli were found in greatest numbers. It will be reiteration to go over the histories of the infants treated in previous years at the sanitarium. In the summer of 1901 nearly five hundred intestinal cases were admitted. These, too, can be roughly divided into the groups just indicated. During that season we were able to obtain more than twenty autopsies. The findings at the postmortem table substantiated those of the cases of our present series which came to autopsy. The intestines of infants observed two years ago suffering from acute toxic affection likewise presented little pathologic alteration. The mucosa was pale and thin, the lymphatic elements in the intestinal wall moderately enlarged, and the mesenteric glands swollen. On the other hand, in a second group of cases the lower bowel was extensively involved, the mucosa being thickened, and often the seat of more or less extensive ulceration, the ulcers beginning usually at the summit of the swollen solitary follicles. The mesenteric glands were hypertrophied. It is an interesting fact that neither in our autopsy findings of last summer nor in the postmortem examinations of the larger series of 1901, was any false membrane found lining the intestines, as is so frequently described in the acute epidemic dysentery of adults.

LEUCOCYTE COUNT.

During that summer the leucocytes in a large number of intestinal cases were examined by Dr. Warfield and the writer.[11] A leucocytosis was found, but the number of white cells varied within such wide limits, even in the mild forms, that a high or low count could not be regarded as of diagnostic value. The differential count, however, showed that while there was no change in the relative ratio of the white cells in the normal infant, in the simple diarrheas, or in malnutrition, that as the case became more severe in type there was a progressive increase in the polymorphonuclear neutrophilic cells and a decrease in the small mononuclear variety, and that this polymorphonuclear leucocytosis took place both in the case of acute intestinal poisoning and in the more severe forms of ileocolitis. The counts made last summer in the series of cases under consideration confirm these results and add some support to the contention that similar varieties of intestinal derangement were under observation.

TREATMENT.

The treatment pursued at the sanitarium followed the usual lines, and will be but briefly referred to. In the acute cases, milk was withheld and sterile water with thin broths, or plain water with a little egg albumin substituted. Whey or whey-cream mixture was found a useful intermediary step to the gradual return to a milk diet. With the chronic cases, milk, beginning with high dilutions, occasionally predigested, often with a cereal water as a diluent, formed the chief reliance. Colon irrigations were frequently given and gastric lavage as the symptoms indicated. Drugs were sparingly used. An initial purge of calomel or castor oil was administered when the baby came early under observation. Various astringent preparations, tonics and opiates were occasionally employed. Injections of salt solutions under the skin were less frequently resorted to than in former years, as it is felt that this procedure has been somewhat over extolled. As stimulants, strychnin, digitalin, alcohol, and atropin were found serviceable in the order named. In the giving of stimulants we were greatly helped by the introduction by Dr. H. W. Cook,[12] clinical assistant, of a modification of the Riva-Rocci sphygmomanometer, by which the blood pressure of the little patients was rapidly recorded. With the additional aid of this instrument at the bedside, Dr. Cook shows that the actual vitality of the infant can be more accurately determined than by the skilled finger on the pulse, and the kind and amount of stimulant suited to the particular need of the hour. Late in the summer we were supplied by Dr. Flexner with an anti-dysenteric serum found protective to laboratory animals. Unfortunately, at this time there were no acute cases at the sanitarium. Several infants ill with ileocolitis, from whose stools the Shiga bacillus had been isolated, were injected hypodermically with 5-10 c.c. of this serum twice a day. No change could be noted in the patient's condition. No untoward effects followed the serum treatment, and it is hoped that more powerful serum in perhaps larger doses will prove to be of therapeutic value, particularly in the early cases.[13]

Enough has been said to make probable the assertion that the infant population of Baltimore during the summer of 1902 suffered from no unusual scourge, but rather was subjected to the accustomed epidemic of diarrheal diseases regularly recurrent during the warm weather, and that typical instances of these disorders were under treatment at the Thomas Wilson Sanitarium. That these infants were not the victims of an infection local to the sanitarium is shown by the fact that they were admitted from all sections of the city already ill. Two cases were from more distant parts of the state. Moreover, since the results of the investigation by Duval and

Bassett have been known, other workers have found the dysentery bacilli in the stools of babies suffering from diarrhea in other localities; thus, Zahorsky,[14] in St. Louis, and Park and Dunham, in a small epidemic at Seal Harbor, Maine, have reported such cases. The extent of epidemics in Japan and in the Philippines indicates that the organism is capable of very wide distribution. Only future research can determine the geographical or climatic limitations of the infection, but it would appear that a large group of the summer diarrheas of infancy are associated with bacilli identical with, or closely related to, *B. dysenteriæ* (Shiga). Recent work by Lentz,[10] His and Russell,[15] Park,[15] and others indicate that minor differences may exist in the cultural properties and startling variations are pointed out in the agglutination reaction of the bacilli isolated from different sources. Thus Park finds that in indol and acid productions, as well as in agglutination reactions, the Japan and New Haven cultures are separated from the Manila, Baltimore, New York and Seal Harbor cultures. Whether, in the search for the cause both of dysentery in adults and of summer diarrhea in infancy, one has to deal with a group of very closely related organisms, or, as is more probable, with slightly different strains of the same bacillus comparable to the differences that can be shown in the various typhoid and colon cultures, is a most interesting and important problem for the bacteriologist to determine.

CLINICAL SIGNIFICANCE OF THE FINDING.

This bacteriologic finding in connection with the summer diarrheas of infancy is of no less interest to the clinician, as it spurs him on to attack with renewed vigor the old problems of prophylactic treatment. Professor Koch,[16] in his notable address two years ago in London, showed the blunder of attempting to treat pestilences according to a general scheme. He said: "Every disease must be treated according to its own individuality, and the measures to be taken against it must be accurately adapted to its specific nature, to its etiology." If the investigations of last summer are substantiated, effort may be directed for the first time against a recognized foe. Questions, then, of the utmost importance can be propounded with some confidence that they will be accurately answered.

METHOD OF PROPAGATION.

One of the first of these problems is to determine the means by which the infectious agent reaches the infant. Although the number of cases in our series is too small to warrant positive assertions, there is some rather suggestive data on this point in the histories of our patients. It can hardly be doubted that the disorders being considered primarily affect the gastrointestinal tract, and therefore that the mouth is the portal of entry, and that the source of infection takes place in the great majority of cases through food or drink, that is, in young infants, through contaminated milk or water. Condition of the milk supplied to the poor from the small stores in our large cities is notoriously bad. During the summer of 1901 Bassett and the writer[17] examined a large number of samples of milk supplied the babies in Baltimore suffering from summer complaint before their admission to the sanitarium. This milk was found to have an average germ content of over four million to 1 c.c., and several samples contained ten to twenty million bacteria in each cubic centimeter. Last summer Schorer repeated and verified this work. He was able to show a progressive increase in bacteria and in diluents in the milk during each stage of its handling from the farmer through various dealers to the baby. Because the milk is so good a culture medium in the warm weather without proper refrigeration, a small initial contamination is sufficient to render it in a few hours unfit for infant feeding.

For the explanation of the sudden outbreaks of this illness at the same time in different sections of the community, one is tempted to turn to a general source of infection. The dysentery organism is related biologically to the colon and typhoid bacillus which are usually conveyed to man through water.

With this thought in mind, an effort was made to find out the character of the water supplied to our patients. The mothers were asked specifically whether the water used in preparing the nourishments, and what is just as important, that supplied to the infants between feedings, was boiled. Concerning but twenty-eight out of the forty-two babies was fairly reliable information obtained as to both the milk and the water used. In twenty-six of these cases unboiled city water was given the babies, either with their nourishment or separately, and in but two instances was all the water supplied boiled. Of particular interest are four infants ill with this specific diarrhea, who were exclusively breast-fed, but to whom unboiled water was given between nursings. Four other babies whose only food was condensed milk, were likewise given unboiled water between feedings. These cases are too few to admit of generalization, but they do suggest that the dysentery, like the typhoid bacillus, may be harbored in the public waters. Indeed, it is possible that infection of the milk with the organism is brought about through dilution with impure water. It is possible to conceive that the disease may be propagated in other ways. Outbreaks of this form of summer diarrhea in asylums and hospitals, where sterilized milk and boiled water are used, are probably brought about by the spread of the disease from patient to patient, through carelessness on the part of attendants. Another source of danger is insects, particularly the common house fly. In the only case in our series contracted at the sanitarium infection was probably conveyed through flies. The child concerned was fed exclusively on pasteurized milk, and given only sterilized water, but there was no means at hand to adequately protect him from the swarms of flies, which may easily have carried the infective agent from a napkin to his hands or feeding bottle. It is difficult to account for the comparative freedom of infants from this form of illness during cold weather and its regular return as a widespread epidemic in summer. Shiga has pointed out that the dysentery bacillus is kept alive in Japan by the occasional sporadic cases which occur during the winter in that country. Evidence suggesting a similar condition among infants in America is accumulating. Thus, in four children brought to the Johns Hopkins Hospital because of diarrhea during January, February and March of this year, the Shiga bacillus was isolated by Bassett, and Ford has lately found the same organism in the stools of a man suffering from a mild gastro-enteritis. By means of such sporadic cases, and because this bacillus may be harbored for months in small numbers in the intestines of chronic cases, it is not destroyed during the winter, but is at hand each summer to rapidly proliferate under favorable conditions. It has been repeatedly emphasized that infants suffering from marasmus, less severe forms of malnutrition, and from other chronic ailments, are its readiest victims.

The name, "dysenteria infantum," or "infantile dysentery," is suggested for the infection under consideration. This designation would distinguish these cases from other forms of intestinal disorder, and also from the specific dysentery of adults, which, although having the same etiology, seems to present clinical and pathologic differences.

From the foregoing discussion, it may be fairly concluded that:

1. The diarrheal disorders of a large series of children treated in the Thomas Wilson Sanitarium during the summer of 1902 were produced by a bacillus thought to be identical with the *B. dysenteriæ* (Shiga).

2. The cases in this series presented the clinical and pathologic features of the several forms of the summer diarrheas of infancy.

3. There is good reason for the confidence that a proportion, and probably a large one, of the so-called summer diarrheas of infancy is caused by the *B. dysenteriæ* (Shiga).

4. A confirmation of the work of Duval and Bassett by establishing the etiology of this yearly epidemic among infants, will make possible the use of more intelligent measures to control and suppress it.

5. More success can be expected from prophylactic measures and from medicinal and serum therapy than ever before.

OTITIS MEDIA IN INFANCY.

JOHN LOVETT MORSE, A.M., M.D.

Instructor in Diseases of Children, Harvard Medical School; Assistant Visiting Physician at the City Hospital and at the Infants' Hospital.

BOSTON.

Many papers have appeared on this subject within the last few years. Nevertheless, my experience leads me to believe that the profession, as a whole, does not realize as it should the frequency of this condition in infancy and its importance in differential diagnosis. I have learned to look for it in all cases of doubtful diagnosis and to consider it as a possible cause for any symptoms not otherwise easily explainable in the course of other diseases. No physical examination in infancy in which other definite signs sufficient to account for the symptoms are not found should be considered complete without an examination of the ears. Many awkward mistakes would also be avoided if they are examined even when the signs of other conditions are present.

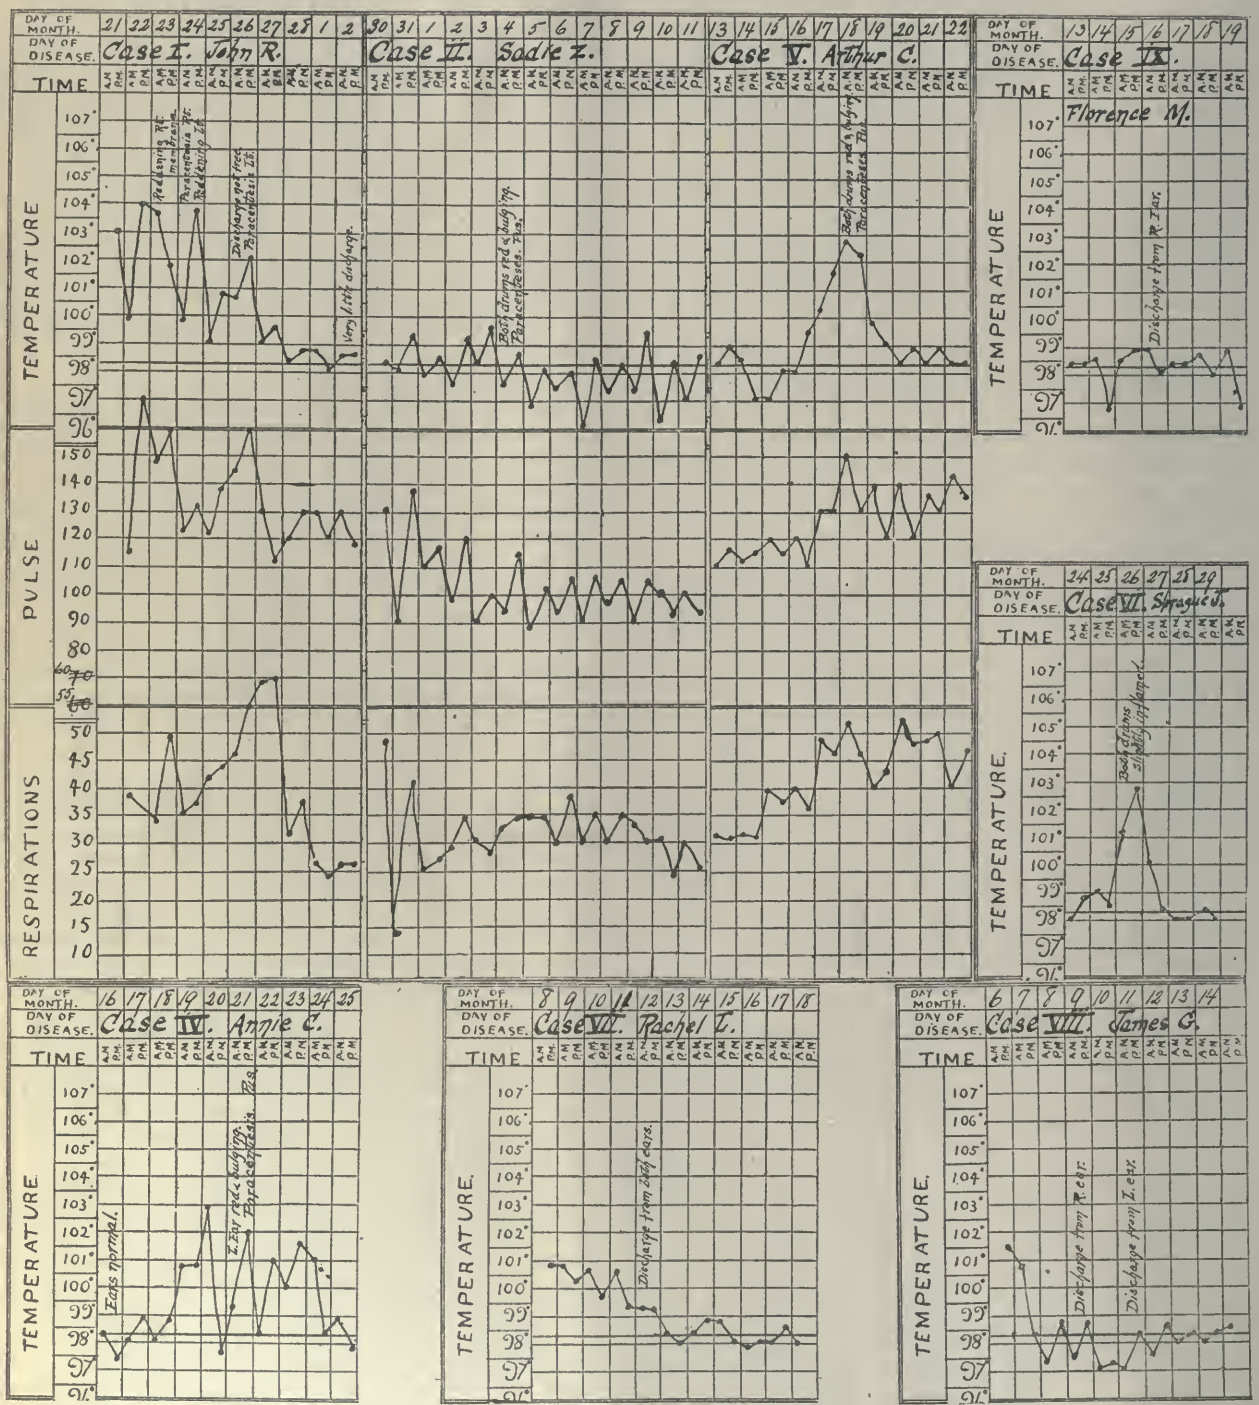
Many physicians seem to think that inflammation of the middle ear is always associated with earache, and hence if there are no evidences of earache they do not consider the ears at all. This view is certainly not justified. Many infants with acute inflammation of the middle ear show no signs of pain at any time, and many others who evidently have pain somewhere show nothing by their actions which will direct the attention of the physician to the ear. It is a common impression that putting the hand to the ear means earache. It sometimes does, but more often does not. All sick babies are very likely to wave their arms about, grab at their ears and pull their hair. Apparent tenderness on pressure over the mastoid is another most unreliable guide. Tenderness over the mastoid is unusual anyway, in simple acute inflammation of the middle ear, and, on the other hand, most sick babies will cry if firm pressure is made on any part of their body. The only way to determine satisfactorily whether or not there is inflammation of the middle ear is to examine the ear with a speculum; all other methods of examination are incomplete and necessarily misleading. The examination of an infant's ears is not a simple matter and requires considerable experience. The results, however, are well worth the time required to master the technic. A smaller speculum than comes with most sets is necessary.

Acute inflammation of the middle ear is usually, but not always, associated with fever, which may be high. It causes many reflex symptoms, which are sometimes quite severe, convulsions not being very uncommon. These reflex symptoms very often attract the attention from the real seat of the trouble to some other part of the body. Meningitis, pneumonia, gastritis, worms, dentition and, in fact, almost every acute disease but the right one is suspected.

An acute primary inflammation of the middle ear is, however, probably more often mistaken for pneumonia than for any other condition. The following case is an example. It also shows very well the results of treatment.

CASE 1.—John R., 6 months old, was taken suddenly sick February 18 with fever, cough and difficulty in breathing. He lost his appetite, but showed no other symptoms of gastro-enteric disturbance. He was taken to a physician February 21, who found the temperature 104.2 F., the pulse 160 and the respiration 52. He sent the baby to the Infants' Hospital with the diagnosis of pneumonia. The physical examination was not made until the next day.

He was a large, fat baby. The color was good. The alæ nasi did not move. The fontanelle was level. There was a slight rosary. The heart and lungs were normal. The abdomen was full and somewhat tense. There was an umbilical hernia. The liver was normal, the spleen not palpable. The extremities were normal, the knee-jerks equal and lively. Kernig's sign was absent. The temperature was 100 F., the pulse 115, and the respiration 38.



While the picture was not that of a pneumonia and the lungs were negative, the disproportion between the rate of the pulse and that of the respiration pointed to a certain extent to some pulmonary trouble. The rapid rise in the temperature and pulse rate that night, while the rate of the respiration remained the same, pointed strongly against it, however.

The next day, the 23d, the ears were examined and considerable reddening of the right membrana tympani was found. On the 24th it was bulging. Paracentesis was performed and a small amount of pus let out. The left drum was also reddened but did not bulge.

The temperature immediately dropped and showed a tendency to run lower. On the 26th, however, it rose again, as did the pulse and respiration. The respiration again rose out of proportion to the pulse. Nothing could be found in the lungs, however. Examination of the ears showed that the right was not discharging freely and that the left drum was bulging. Paracentesis was done on the left ear and the discharge re-established in the right. The temperature and pulse

dropped immediately and were followed in twenty-four hours by the respiration, all remaining normal afterward.

In the following case the symptoms were most unusual and misleading, all pointing to some obscure cerebral condition, either acute or chronic. The true condition was not suspected, although the patient was seen by a number of men, all of whom were well aware of the importance of ear disease in infancy as well as of the variety of its symptomatology.

CASE 2.—Sadie Z., aged 15 months, had a good family history. There was no history of nervous or mental disease or anything to suggest syphilis. She was delivered by instruments, the head presenting, and was normal at birth. She had always been well except for chicken-pox at thirteen months. Her parents said that she was unusually bright mentally. She had walked alone for a month or more.

On December 13 she tripped on the floor and fell, striking her head on a chair. She did not appear to be much hurt. About this time she began to have a slight cough. December 22 she began to have "convulsions," which continued up to the time of entrance to the Infants' Hospital, December 30. The cough continued and she vomited several times daily. The bowels moved daily and the movements were normal.

She was well developed and nourished. There was moderate pallor of the skin and mucous membranes. The head was of normal shape. The anterior fontanelle was about 1.5 cm. in diameter and slightly depressed. She did not open the left eye quite as widely as the right, but closed both vigorously. The motions of the eyes were normal and the pupils reacted quickly to light. She both saw and heard. She had five teeth. Her tongue was clean. There was no rosary. The heart, lungs, liver and spleen were normal. The abdomen was nega-

tive. There was no rigidity of the head or spine. There was no spasm or paralysis of the extremities. The knee-jerks were equal and somewhat exaggerated. Kernig's sign was absent. The inguinal glands were slightly enlarged, the cervical and axillary were not. The urine was pale, acid, of a specific gravity of 1008 and contained no albumin.

She slept well and was perfectly quiet when asleep. When awake there was almost always a tremor of the head and arms, although she was sometimes quiet for a short time. This tremor was rhythmical and very rapid. It was most marked in the head and arms, although it was also present in the body and legs. She was very easily excited and frightened. She then became rigid and threw herself about, crying loudly. The cry was interrupted at short intervals, but the rhythm was much less rapid than that of the tremor. In these attacks the tremor was much more marked and more rapid. In some of the attacks there was also nystagmus, usually lateral, but sometimes vertical.

The temperature was normal at entrance and never went above 99.6 F. The pulse and respiration were somewhat rapid for the first two days, but after this showed nothing worthy of note.

Her stomach was washed out and her bowels emptied with castor oil. The vomiting ceased at once and did not recur. The movements were normal. Moderate doses of bromid and chloral had no effect. Her condition continued unchanged and there was no change in the physical signs. The fundi of the eyes showed nothing abnormal.

She was seen by three specialists in nervous diseases, all of whom agreed that the fall was a coincidence and that there was no acute cerebral process. They said that the history of normal mental development must be wrong and only a congenital cerebral defect could account for the symptoms. The medical men who saw her did not agree with this diagnosis, but also ruled out meningitis and injury as the cause of the symptoms. They were, however, unable to make any diagnosis.

Her ears were examined January 4 as part of a routine examination of all the babies in the hospital. Both drum membranes were generally reddened and bulged in their upper posterior portions. Paracentesis showed pus on both sides.

Improvement was almost immediate and after the first few days was very rapid. The ears were normal on January 14 and she was discharged well a few days later. There has been no return of the symptoms.

In certain other cases of a more subacute type the symptoms are those of confined pus. The hectic temperature, often associated with chills, and the apparent absence of a local cause often lead to the diagnosis of tuberculosis or malaria.

CASE 3.—Joseph B., 22 months old, was seen July 22. He lived in a malarial district. He had always been delicate and pale. He had had a cough since an attack of bronchitis in the early spring. He had also had a slightly elevated temperature since that time. During the last two weeks he had seemed worse and the temperature had ranged higher. The night before he had had a chill, followed by a temperature of 105 F. and sweating. Nothing abnormal had been found on physical examination except pallor and a slight enlargement of the spleen. The urine showed nothing abnormal.

An almost positive diagnosis of malaria had been made on the basis of the chills, fever and sweating, the enlargement of the spleen, the pallor and the apparent absence of any other cause for the symptoms. Examination of the blood, however, showed no plasmodia and 30,000 white cells, a finding entirely inconsistent with malaria.

An examination of the ears, which had hitherto been overlooked, disclosed the seat of the trouble. Pus was found on both sides and evacuated. Improvement was continuous and rapid from that time.

Acute secondary inflammations of the middle ears are far more common than the primary forms. They occur most frequently, of course, as complications of diseases of the respiratory tract, especially when the upper air passages are involved. They are especially likely to be overlooked and their symptoms misinterpreted when the disease is mainly pulmonary, all the symptoms being attributed to the local process in the lungs. The following cases show the importance of being on the lookout for ear complications in these diseases.

CASE 4.—Annie C., aged seven months, was admitted to the Infants' Hospital March 4. She had the signs of a diffuse broncho-pneumonia on the right side, and those of a general bronchitis on the left. She was also poorly nourished and slightly rachitic. The temperature fell to normal on the 6th and there remained. The general condition improved and the lungs cleared up, except for a few râles in both backs. A routine examination on March 16 showed that the ears were normal.

There was a sudden rise in the temperature, pulse and respiration on the 19th. A recrudescence of the broncho-pneumonic process was of course suspected. Nothing new was found in the lungs, however, either then or later. Finally on the 21st the ears were examined, and the left drum found red and bulging. Paracentesis let out a small amount of pus. The temperature continued irregularly elevated for several days and then dropped to normal, where it remained.

CASE 5.—Arthur C., aged seven months, was admitted to the Infants' Hospital February 28, with broncho-pneumonia. On March 14 there was dulness in the left back with bronchial respiration below the spine of the scapula. Many coarse, moist râles were heard throughout both lungs; they were most numerous at the left base. The temperature was normal and the rate of the pulse and respiration but little increased. A diagnosis of convalescence from broncho-pneumonia was made.

He did perfectly well until March 16, when the temperature, pulse and respiration began to rise, reaching their maximum on the 18th. The rate of the respiration rose out of proportion to that of the pulse. Everything pointed to a lighting up of the process in the lungs. The examination of the lungs, however, showed only slight dulness in the left back below the angle of the scapula with slightly changed respiration and a few coarse, moist râles in both lower backs, a much better condition than four days previously. An examination of the ears showed that both drums were reddened and bulging. Paracentesis disclosed pus on both sides. The temperature fell rapidly to normal and there remained. Nothing developed in the lungs.

Inflammation of the middle ear may develop in any of the diseases of infancy as well as in those of the respiratory tract. They are especially common in conditions of malnutrition, whether or not due to diseases of the gastroenteric tract. The amount of reaction seems to depend a good deal on the general condition of the infant, being less marked in the feebler babies. It is not at all uncommon at the Infants' Hospital to have one-third or one-half of the babies with serious disturbances of nutrition develop middle ear inflammation. The following cases are examples:

CASE 6.—Sprague J., 3½ months old, had always been improperly fed and had always had colic, vomiting and diarrhea. He had recently lost weight pretty rapidly. He was admitted to the Infants' Hospital March 12.

He was fairly developed and nourished, but rather pale. The physical examination was negative except for a slight rosary. A routine examination of the ears a few days after entrance showed nothing abnormal.

He responded very quickly to proper food, stopped vomiting, and after a few days had normal movements. He did not gain in weight, however.

On March 26 the temperature suddenly rose to 102.8 F. The pulse and respiration did not rise, however, and no other symptoms developed. Nothing abnormal was found on physical examination until the ears were examined, when both drums were found slightly inflamed. No treatment was in-

stituted. The inflammation in the ears rapidly subsided in the next 24 hours and with it the temperature fell to normal, where it remained.

CASE 7.—Rachel L., five weeks old, was admitted to the Infants' Hospital June 8. She had always been improperly fed, had always vomited and had green, watery movements. She had lost weight rapidly during the week before entrance.

She was small and thin. The skin was mottled and the extremities cold and slightly blue. The anterior fontanelle was depressed and the cranial bones overlapped. The abdomen was distended. The examination showed nothing else abnormal.

She took her food well and vomited a little, but had three or four green, watery movements with curds and mucus daily. The elevated temperature, which varied between 100 F. and 101 F., was attributed to enteric disturbance.

Both ears began to discharge on the 12th. The temperature immediately fell to normal, where it remained. As there was no improvement in the condition of the digestive tract the fever must have been due to the process in the ears.

While middle ear disease in infancy usually causes some symptoms, even if nothing more than a slight rise in the temperature, it may develop and go on to perforation of the drum membrane without producing any symptoms whatever. This happened in the two following cases. They suggest strongly the advisability of routine examination of the ears in all sick infants, no matter what the disease or whether or not there are symptoms pointing to aural trouble.

CASE 8.—James G., aged 2½ years, entered the Infants' Hospital just on the crisis of a lobar pneumonia. The temperature did not rise again and the lungs cleared up rapidly. He presented no symptoms whatever suggesting trouble in the ears or elsewhere, yet three days after entrance the right ear began to discharge, and two days later the left ear.

CASE 9.—Florence M., aged three months, entered the Infants' Hospital March 7. No history came with her. She was emaciated and the skin was mottled. The anterior fontanelle was small and depressed. There was a slight rosary. The physical examination was in other respects negative.

She took her food well, seldom vomited, had nearly normal movements and gained in weight. She had no fever at any time and showed no symptoms pointing to aural trouble. Nevertheless a discharge from the right ear appeared March 16.

In conclusion, I wish to thank Dr. T. M. Rotch for permission to make use of such of the cases as were on his service. The examinations of the ears, as well as the operations, were done by Dr. E. A. Crockett, aurist to the Infants' Hospital.

LOCOMOTOR ATAXIA

COMPLICATED BY THROMBOSIS OF THE PONTILE ARTERIES, WITH REPORT OF CASE.

S. D. HOPKINS, M.D.

Neurologist to St. Anthony's and Denver County Hospitals, and to the Mercy Sanitarium.

DENVER.

W. R. M., male, admitted to St. Anthony's Hospital June 5, 1899, aged 45, traveling salesman, born in New York, in Colorado fifteen years. Family history negative.

Previous History.—Had the usual diseases of childhood, after which he enjoyed good health until he was fifteen years of age, when he met an accident, fracturing his right leg. At 20 years of age he contracted gonorrhea. When 40 years old he suffered from severe pains in the legs, which were sharp, shooting and momentary in character and were influenced by changes in the weather. About the same time he noticed that his gait was gradually becoming unsteady and at the present time he is unable to walk in the dark without falling. Three years ago he complained of a girdle sensation, also difficulty in starting his urine to flow, although while asleep the urine dribbles from him. During this year, while alighting from a street car, he fell, striking his buttocks without any serious consequences. For the past two years vision has failed, but he never sees double.

Bowels regular. Denies alcoholism. Had syphilis when 25 years of age. Several months before his present trouble manifested itself he suffered from headaches and dizziness, but did not have any transitory weakness on either side of the body.

Present Illness.—Began thirty hours previous to being admitted to the hospital. After eating a very hearty breakfast he suddenly became so dizzy that he was unable to remain in the erect posture, also suffered from numb and tingling sensations in hands and feet, more marked on right side of the body. At the same time complained of a sharp shooting pain over the left eye, which was momentary and recurred at intervals. The dizziness, numb and tingling sensations continued for ten or fifteen minutes, when he noticed that he was unable to swallow, although he was able to talk, but his voice was weak. At the same time he complained of weakness of the right arm and leg, although he was able to walk. At no time during the attack did he lose consciousness.

Examination.—There is marked ataxia in legs and arms and slight in the trunk muscles. On assuming the upright posture the dizziness is so great that he falls to the floor. Knee jerks: right, absent; left, same. Ankle clonus, absent. Tendo achillis: right, slight; left, slight. Deep reflexes of forearm: right, present; left, same. Masseter, absent. Plantar reflexes, increased. Cremasteric: right, increased; left, absent, probably due to the presence of a large scrotal hernia. Abdominal, absent. Muscular power in right arm and leg very much diminished compared to the opposite side. Tactile, joint, pressure and muscular senses present.

Pain sense: He is unable to distinguish the difference between a dull or a sharp point on the right side of the body, nor is pain complained of when pricked with a sharp point. Throughout the left side pain sense is present. Temperature sense is lost on the right side, but is present throughout the left side. Muscular power in the lower portion of the face decidedly impaired and the mouth is drawn to the right. Voluntary movements are more affected than emotional. Tongue deviates to the left. Left side of palate hangs much lower than right and on tickling the left side no reflex is produced, although it is readily elicited on the opposite side. Respiratory movements decidedly increased. Voice very husky, but every word pronounced distinctly. Dynamometer: right, 50; left, 66.

Pupils: right is larger than left and both respond to accommodation, but not to light. External ocular movements good. Fundi and fields of vision normal. Hearing: right (watch) heard on contact; left, 12/24. Taste: present on right side; absent on left. Smell: present on right, and absent on left.

July, 16, 1899. Patient is able to swallow liquids, but insufficient to sustain life.

July 23, 1899. Is able to take soft food and liquids. Feeding by tube resorted to occasionally.

July 30, 1899. Use of the tube unnecessary. Dizziness still present. Examination of heart shows an aortic systolic murmur. Urine, sp. gr. 1021, no albumin or sugar.

This case is of interest from two points of view, as the symptoms indicate that the brain and spinal cord are involved. The symptoms from which the patient suffered previous to his present trouble are characteristic of degeneration of the spinal cord, although the motor form of multiple neuritis must be considered in making a differential diagnosis. The presence of the Argyll-Robertson pupil, girdle sensation around the trunk and involvement of the sphincters would be sufficient evidence that the lesion is in the cord. The absence of paralysis of the extensor muscles, tenderness of same and the disease not being distinctly peripheral, symmetrical and bilateral and without reaction of degenera-

tion, would exclude inflammatory affections of the peripheral nerves. In ataxic paraplegia the ataxia is preceded by a spasm of the muscles, increase of the knee jerks, and the absence of sensory symptoms would be sufficient to eliminate this disease in arriving at a conclusion. The length of time the symptoms have existed would exclude all acute lesions of the cord. The patient suddenly became affected with dizziness, which was so intense that he was unable to assume the upright posture, with paralysis of the lower left side of the face and paralysis of the right arm and leg, associated with disturbance in sensation of the same side of the body. At the same time he had loss of power in deglutition, loss of sensation on the left side of face and mouth, with loss of taste and smell on the same side.

All these symptoms indicate that the secondary lesion is in the brain, and to determine its probable nature it is best to consider some of the acute, chronic and sudden diseases of this organ. The time consumed in the development of the symptoms in this case, without any elevation in temperature, would enable one to pass all inflammatory diseases of the encephalon.

The chronic lesions are morbid growths, abscess and aneurism. The history of this case and the non-involvement of the optic nerves by inflammation, with the resulting atrophy, would exclude aneurism and morbid growths.

The onset of the symptoms which complicated the locomotor ataxia was sudden, reaching its height in a few minutes; excluding traumatism, all such cases are vascular in nature.

The vascular lesions to be considered are hemorrhage, embolism and thrombosis. Absence of a full, strong pulse, throbbing carotids, loss of consciousness and slight disturbance in bodily temperature would not be in favor of cerebral hemorrhage. Small or gradual hemorrhages may occur without marked disturbances in consciousness, with slight paralysis and without great disturbance in the bodily temperature.

On admission to the hospital the symptoms in this case were extensive without any involvement of consciousness, and the exclusion of a hemorrhagic lesion is justifiable.

In cerebral embolism the symptoms come on suddenly, with marked disturbance in consciousness, associated with some form of cardiac disturbance, and without the latter one is not justified in arriving at such a conclusion. The patient under discussion has an aortic systolic murmur, but cardiac compensation is well maintained and an embolus affecting the portion of the brain where this lesion is located would produce sudden profound unconsciousness, with bilateral involvement of the extremities, without any premonitory signs, and the symptoms produced would depend on which portion of the basilar artery was affected.

The upper portion of the basilar artery is most frequently occluded by an embolus, and the symptoms manifested may simulate those of locomotor ataxia to a certain extent, particularly the ocular symptoms, but differ from those produced by a vascular lesion by being transient and associated with paralysis of the opposite side of the body.

The diagnosis of thrombosis was, therefore, made on the following symptoms: premonitory symptoms, headache, dizziness, with numb and tingling sensations in the parts subsequently paralyzed. The paralysis came on suddenly without loss of consciousness and with the characteristic disassociated symptoms in the affected parts.

A lesion of the cerebral cortex, centrum ovale and internal capsule can be excluded by the character of the paralysis and the presence of the disassociated symptoms, along with disturbance of deglutition and involvement of other cranial nerves. Disturbances in the brain at any of these locations would produce a monoplegia or hemiplegia on the opposite side of the body and if it is a hemiplegia the paralysis would not be crossed.

Affections of the crura are always accompanied by paralysis of the third nerve on the side of the lesion, with motor paralysis on the opposite side of the body.

The symptoms produced by lesions in the medulla are usually bilateral and from the number of cranial nerve centers affected, the patient would present symptoms similar to those found in bulbar paralysis, excepting that sensory symptoms are more frequently associated with the motor manifestations in vascular disease of this organ. Lesions in the pons produce all the symptoms which are present in the case under discussion, and it is of interest to know which portion of the pons is affected. Diseases in the extreme upper portion of the pons can be excluded, as we have no involvement of the third nerve nor crossed paralysis. The symptoms in the case are complex and show that the lesions are multiple.

If the disease was below the middle of the pons it would cause crossed paralysis, but the upper and lower portion of the face would be affected. Lesions just above the middle of the pons would produce paralysis of the lower portion of the face on the same side as the lesion with disturbance in motion and sensation on the opposite side of the body in the form of disassociated symptoms (loss of pain and temperature sensations, while tactile sense is preserved).

Loss of taste, smell, rapid respiratory movements and the inability to swallow may be accounted for by the involvement of the extreme lower portion of the pons and upper part of the medulla oblongata.

Vascular lesions in this position, after the irritative symptoms have ceased, can be more accurately located than other diseases, particularly tumors, as in the latter the irritative symptoms remain throughout their course.

The symptoms demonstrate that a number of vessels are affected and that they are those which supply the pons just above the middle, the extreme lower portion and the upper part of the medulla oblongata.

The character and extent of the symptoms indicate that the small arteries are affected inasmuch as those produced by involvement of the large vessels would be more extensive, with marked disturbance in consciousness, and bilateral in nature.

Causes of cerebral thrombosis are many, and the most prominent are atheroma, syphilis and blood states. No evidence of atheroma could be discovered in any of the superficial vessels in the body, and with a distinct history of specific infection one is justified in attributing the occlusion of the vessel to a syphilitic arteritis.

The large vessels at the base of the brain show the greatest changes in their walls, but the narrowing of the caliber of the artery is more pronounced in the small branches.

The changes that take place in the walls of the diseased vessels consist of inflammation, swelling and a gummatous deposit and, as a result, a lessening of the caliber.

Occlusion of an artery in thrombosis goes on gradually, but the final and complete plugging comes on suddenly by the formation of a blood clot.

A NEW METHOD OF BACTERIAL VACCINATION.

As is well known, bactericidal sera, in contrast to antitoxic sera, have been extremely disappointing from the view-point of therapeutics. None, even the antistreptococcus serum, has an unassailable position in the treatment of disease in man. Experimental animals may in some cases be given a temporary immunity to certain bacteria of several days' to two weeks' duration. But the serum is rapidly excreted, and takes with it all its protective powers, i. e., its specific amboceptors. Even in this case it is a prophylactic injection, and not a curative. In view of the transient duration of the immunity conferred by an injection of bactericidal immune serum, its indiscriminate injection during an epidemic would probably be unjustified. On the other hand, bacterial vaccination, such as that of Haffkine against plague, while it appears to have been of value, has the objections that it often produces grave symptoms, is followed by a short period of decreased immunity, and if it should happen to coincide with an attack of the disease would probably seriously injure the patient's chances of recovery.

With the view of overcoming the disadvantages of the Haffkine injections, Besredka[1] injected a culture of an organism which had been treated with the specific amboceptors for that organism. It will be recalled that amboceptors are the intermediary bodies that bind the complement to the bacilli. The amboceptors resist heat, low degrees of which (56 C.) destroy complement. For example, a culture of the typhoid bacillus was suspended in salt solution and enough heated antityphoid serum added to cause complete agglutination. The mixture was allowed to stand for six hours, during which time the bacteriolytic amboceptors, as well as the agglutinating bodies, are fixed to the bacteria. The bacteria were then washed free of serum by repeated centrifugating in salt solution. The sediment, consisting of typhoid bacilli plus the immune bodies, was then injected into animals. It was found that immediate immunity was conferred, which endured for at least five or six months. No general or local symptoms followed the injection; and this was true of an injection Besredka made in himself. The same experiments were made with cholera and plague; in working with the latter killed organisms were used.

1. Besredka: "De l'immunization active contre le peste, le choléra et l'infection typhique." Ann. de l'Inst. Past., xvi, 1902, p. 918.

Of equal interest are the results of Marie,[2] who used the technic of Besredka in experimenting with rabies. For injections he used the brain of an animal which had died of rabies. The brain was subjected to the action of antirabic serum as the bacteria were to the action of the antibacterial serum. Also here a single injection conferred immunity which lasted for a number of months, the maximum duration not being determined.

The value of this method of prophylaxis over the Haffkine injections is apparent. As to rabies, it would apparently have advantages over the classical Pasteur method of treatment. However, it would require great courage to inject a fresh rabic brain into a human being, no matter how many antirabic amboceptors it may contain. In addition it is quite possible that a mixture which is harmless to a rabbit may not be a neutral one for man. It may be possible that in bites on or near the face, where the incubation period of rabies may be shortened, this method would be superior to the usual Pasteur treatment. If Besredka's results find sufficient confirmation, it would not be altogether impracticable, though difficult, to immunize whole communities against typhoid, cholera or plague.

AMERICAN RESEARCH AND GERMAN REVIEWERS.

There is no contributor to American biologic literature in the branches of medicine and the allied sciences, who has not had occasion to note the marked disregard of German writers for contributions that do not bear the mark "made in Germany," this being particularly noticeable when it concerns work published in this country. Time was when we felt hurt that our struggles to do good honest research were not appreciated, perhaps not believed, by those to whom we owed most of our foundations in science. Now the situation has changed. With our new wealth of production, its best undoubtedly of the very highest quality, we are inclined to merely wonder when the Teutonic awakening is to come. How long before the German will appreciate that if other peoples are diligently reading all that he is producing as well as that of their own countries, while he limits his view to German scholarship, he will soon be at a hopeless disadvantage? As we see the German surgeons discussing points in the pathology and treatment of appendicitis that were long ago hackneyed to us; or read frightful tables of mortality from operative methods in tuberculous hip joint disease that American surgeons have happily forsaken for better measures, we appreciate that the teacher can never afford to neglect to watch the products of the pupil. And when a German reviewer[1] attempts to make a "zusammenfassendes Referat" of the work done on the subject of intestinal digestion without the slightest knowledge of the important contributions of Hill and of Kastle and Lovenhart, merely because they were printed in the English tongue, there is good ground for

1. Biochemisches Centralblatt, 1903, I, 169.

feeling that we are by no means the chief losers because of the lack of German recognition.

An American writer recently took the trouble to write to a German scholar to inquire why he had omitted certain fundamental articles published in America, in reviewing the literature of a certain subject. More amusement than chagrin was elicited by the reply; for, in addition to stating with great complacency that he had not seen the articles in question because the journal containing them was not to be found in the small university town in which he resided, this German in a most benignant manner made the suggestion that if American scientists wished their papers read they should print them in German. It was with no little pleasure that the American in reply could quote figures as to the relative numbers of English-speaking and German-speaking people of the world, with a few additional remarks as to the importance of considering rate of growth in determining the status of any particular subject. The figures really made it seem that there were quite a few people who could read a paper published in English. We have recently heard much of Chauvinism in medicine as synonymous with what has also been termed the arrogance of provincialism. Is not Chauvinism likely to become a danger to that glorious German scholarship that has had no greater admirers or more eager followers than the American scientists?

It is pleasing to observe the occasional reverse of the above conditions, and to see that in some subjects, at least, we are appreciated. Rudolf Höber[2] quotes twenty-nine references in a review of the topic of the rôle of the neutral salts in protoplasmic activity, and of these twenty-one are by American and English writers, published partly in German and partly in English. This Anglo-Saxon predominance is, of course, attributable to the work of Loeb and his scholars, who have easily accomplished the greatest advances in this new field of biologic research. The custom followed by Loeb of publishing part of his work in Germany and part in America, would, if generally adopted, soon compel Germans to search in American publications, but we must insist that there is no particular obligation or need to show them what we are doing. Theirs must be the loss that is bound to fall on those who fail to appreciate that science is cosmopolitan and polyglot. We must also note that American publications are not alone overlooked; English work also seems to escape German eyes. French reviewers, on the other hand, as a rule, cover our publications much more thoroughly, and the admirable abstract department of certain French journals gives ample consideration of all the leading American journals. With our many magazines of medical science overwhelmed with articles reporting actual research we may hope the terse German summary of "Nichts neues" that has so often appeared under an American title, will soon disappear. To the justice of the use of this summary in so many instances hitherto we must attribute, in all honesty, much of the present German oversight, but at the same time we insist that the need for its use is passing. We are doing much work that is "Etwas neues," not to mention "einwandsfrei."

THE FROUDE-CARLYLE CONTROVERSY.

As the Froude-Carlyle controversy has taken a medical turn, it will not be out of place to refer to the matter in these columns. It will be remembered that about twenty years ago Froude, in editing Carlyle's reminiscences and letters, made Carlyle appear as a cruel and inconsiderate husband and his wife as a martyr, at least it so appeared to one side in this controversy. The whole question once so earnestly discussed has again been brought before the public by the appearance of a series of letters of Mrs. Carlyle.[1] Not the least interesting part of these two volumes is the long introduction by a well-known London medical man, Sir James Crichton-Browne. With wonderfully vigorous English he defends Carlyle against the charges of cruelty and neglect, and denounces Froude as an incompetent editor who was not only careless, but who maliciously misrepresents in order to prove his point, viz., that Mrs. Carlyle was abused. These new letters strongly supported Sir Crichton-Browne's contention.

But the matter did not rest here. Goaded by the stinging words of Crichton-Browne and the editor, Alexander Carlyle, son of Thomas, Froude's relatives have now published a pamphlet written by Froude and found among his papers.[2] In this Froude directly charges the antagonism to his editorship to the fact that the Carlyle relatives felt that they, and not he, should reap the financial reward arising from the publishing of the Carlyle papers. But more than this, he declares that the true cause of the unhappy home life of the Carlyles was its lack of children, and that for this Carlyle was to blame. In a word, Carlyle was impotent. To this charge Sir James Crichton-Browne replies, and very appropriately in the pages of a medical journal,[3] by declaring that the cause of the childlessness lay probably in Mrs. Carlyle. She was, he believes, sterile. He shows by well-chosen argument, some of it amounting to proof, that Carlyle was not unfit physically to be a husband. To any one who will read the letters of the first few years of their married life it will seem incredible that their relations were merely those of "companions." We omit the details of the pamphlet and of Crichton-Browne's rejoinder. It is truly shocking to think of this dissection of one's home life and of a public discussion of the most intimate marital relations. It is disgusting. As the *London Times* has said, what the Froude relatives have done "is a serious offense against reverence for the dead, if not against decency and decorum."

1. New Letters and Memorials of Jane Welsh Carlyle, London and New York, 1903.

2. Froude: My Relations with Carlyle, London and New York, 1903.

3. British Medical Journal, June 27, 1903.

We prefer to look upon the Carlyle household as not angelic but as human. Two strong-minded individuals, their marriage unfortunately unblessed by children, living under the same roof for twenty-four hours of the day —for the home was also Carlyle's place of business, his literary workshop—both sufferers from physical ailments, both of strong likes and dislikes, is it any wonder that there were occasional storms? Carlyle growled and his wife snapped back. The course of true love evidently did not run smooth in the Carlyle family. And the ill health of this couple may explain much of the apparent unhappiness.

Carlyle was a dyspeptic, or perhaps had eye-strain, as Dr. Gould contends. At any rate he had headaches and felt out of sorts at times. Mrs. Carlyle was a neurotic, as her mother had been before her. In fact she and her mother got along very poorly when they were together. Mrs. Carlyle had severe sick headaches, "such headaches I never witnessed in my life," writes her husband. She was a neurasthenic. She dosed with all kinds of drugs and took freely of opiates for the relief of pain. Carlyle says: "When any new miraculous kind of doctor was recommended as such my poor, struggling martyr, conscious, too, of grasping at mere straws, could not but wish to see him; and he came, did his mischief and went away."[4] Even "magnetizers" were tried.

Physicians are familiar with this type of woman and oftentimes our sympathy is fully as much with the enduring husband as with the suffering wife. For ten years, according to Sir James Crichton-Browne, Mrs. Carlyle suffered from a climacteric melancholia. Unnecessarily suspicious, morbidly sensitive, racked with physical pain, often under the influence of opiates, her mind, as shown by her letters and by her journal, was lacking in that cool judgment that is found in one well balanced. This was not, as Froude would have us think, all the result of ill treatment by her husband.

The whole controversy has been, to say the least, unfortunate. Especially is this true of the discussion concerning the barrenness of the marriage. The indecency of it all sets the tongues of the prurient wagging and fills the columns of the yellow journals. Altogether, it leaves a bad taste in the mouth.

"KOCH CONSUMPTION CURE" AND NEWSPAPER ADVERTISING.

Some time ago[1] we commented on an exposé by a magazine of the so-called Koch consumption cure concern. Recently the matter has been taken up by the health department and by the physicians of New York City, and the District Attorney, it is understood, has in his possession sufficient information to warrant him in proceeding against the concern, so it looks as if it would soon be in the toils of the law. The health department has issued a statement warning the public against it, and states that the head of the institution is not registered, and has no authority to practice in New York State. The representative of this concern is variously known as Dr. Philip Koch, Dr. Edward Koch, etc., and to avoid the embarrassments arising from violation of the state laws regulating medical practice he is kept moving from one part of the country to another. He is generally in the background after his arrival in a place, and can not be inveigled by strangers to examine them or to receive fees. He is reported to have graduated from the Missouri Medical College in 1881. We are informed that the company is incorporated with a capital of $125,000, that its president is Dr. Wallace Cleveland Clark of 150 Nassau street, New York, and that the manager of the New York branch is Dr. Frank Bigelow, who receives a salary of $80 per week, while his assistant, Dr. Jordan, receives $40 per week. The published correspondence from the concern makes instructive but melancholy reading. Some idea of the immense profits may be formed from Dr. Bigelow's statement that in the month of June, while a poor one, they took in at the New York branch alone $3,500. A part of the testimony taken before Judge Lacombe of New York is stated to show that the magic fluid called "Koch's Inhalation Fluid, or Tuberculine," which costs $10 per month to have it "strengthened," is simply a petroleum oil, colored reddish. Sometimes it is scented with oil of thyme, with oil of eucalyptus or with oil of cinnamon.

While this institution is before the public eye at the present time, it must not be forgotten that it is only one of many such concerns that are using the sick and afflicted as their dupes. There can hardly be imagined anything more base than that of a man deliberately making a business of swindling by fraudulent promises to cure those who are suffering from incurable diseases. Nevertheless there are scores of such individuals and concerns getting rich by like nefarious and execrable practice. One of the most discouraging things is that nearly all of our reputable newspapers are openly endorsing this inhuman business, their columns are defiled by the indecent and vicious advertisements of harmful medical nostrums, and of pure swindles gotten up solely for the purpose of getting the money of the unfortunates whose condition makes them ready to grasp at every straw that offers relief. It is a pity that respectable and influential newspapers should lend themselves to help such frauds just for the few dollars that come from carrying such advertisements. The evil is one that has long existed, but that is no reason why it should continue.

THE DANGER FROM BACTERIOLOGISTS.

A correspondent of our contemporary, the *Cincinnati Lancet-Clinic,* says that it is strongly suspected throughout continental Europe that some bacteriologic laboratory is manufacturing poisons to sell to designing persons at high prices. Such things are possible. It would be easy for one thoroughly accomplished in bacteriologic work, and likewise imbued with the "devilishness" of

4. Reminiscences, N. Y., 1881, p. 481.

1. THE JOURNAL A. M. A., May 9, p. 1295, Vol. xl.

commercialism, to start this kind of a manufactory regardless of consequences. The threat of the Macedonian insurgents to introduce plague into Turkish cities is probably a mere *brutum fulmen,* and their giving away of the plans has disarmed them to a great extent, but it is not difficult to conceive of the mischief that might arise should such plotters act before telling. The danger is one that may yet have to be met, although we need not lie awake nights worrying about it. As long as bacteriologic laboratories are in the hands of high class medical men, the danger is *nil,* but, of course, there is no assurance that others impelled by sinister motives could not take up the work, and no reason why they could not be successful in doing an incalculable amount of harm. But there is no need to fret about it until there is more cause than is apparent now, at least in this country.

DANGER FROM ETHER IGNITION.

The danger of ignition of ether vapor is well known to the profession and due precautions are usually taken against it. In one of our contemporaries, noticed in our last issue,[1] appears an account of a new source of this danger which could not have been ordinarily anticipated. Dr. Dwight H. Murray reports to the *New York Medical Journal* the ignition of ether vapor during an operation by the sudden turning on of an electric bulb light by the anesthetist. How this happened it is hard to say, though his theory is that it must have been due to some action of the electric spark, leakage, we might say, that was sufficient to inflame the combustible gas. That such instances are rare is, of course, self-evident. The fact that the surgeon in question experimented a number of times to reproduce the condition without success leaves a little doubt in our minds as to the actual occurrence of the facts as they appeared to him. It also, however, leaves an uncomfortable little doubt as to the safety of using even electric lights in the presence of ether vapor. Anesthetists will doubtless take heed to this unique experience and govern themselves accordingly.

SYPHILIS AND SUICIDE.

In a recent article Fournier discusses the connection of suicide with syphilis. He has had in the course of his observation some eighteen cases of suicide in syphilitics, in all of which the disease seemed to have a direct connection with the act. He has known of eight cases of suicide on account of the disfigurement, either from syphilitic lesions or some trifling lesion which the subject regarded as a sign of worse to follow or mistook for syphilis. The mental condition of those suddenly learning of the infection may lead to what might almost be called a reflex suicide. Fournier says that he has more than a hundred times seen strong men turn pale, sink down, and sometimes even lose consciousness from shock when told that they had the disease, and this in subjects otherwise unimpressionable and intrepid in danger. It is his experience that women display much more equanimity in regard to the disease than do men; it has a less mental effect on them when acquired. He strongly condemns brutal declarations of their condition to the patients; the announcement should be guarded and gradually led up to; doubt should be expressed at the first or second examination, and if the patient is informed of his condition it should be followed by the statement that it is not severe, and that it is controllable, if not curable. In case of intending marriage, however, the physician's duty is imperative.

1. THE JOURNAL A. M. A., July 11, p. 131.

IMMUNIZATION AGAINST TUBERCULOSIS.

The rather remarkable address of Maragliano on "The Struggle and Immunization of the Organism Against Tuberculosis" at the Madrid Congress has been noted in abstract in this journal.[1] It has also been republished[2] in this country, and has excited more or less public attention. The lay press has taken the subject up and discussed it with its usual mixture of lucidity and misunderstanding. Naturally, the statement that an investigator has obtained a vaccine which will produce immunity in the human subject against tuberculosis is a stirring one, and especially since at the present time the public generally, and we might also say many physicians, have a rather exaggerated idea of the importance and fatality of this disease. Those who have prophesied the eradication of tuberculosis will take up these statements and see in them a forecast of results they have predicted. It seems to us, however, that we may overestimate the importance of these announcements, and that it is worth while to at least accept them with some reservation until further experimentation and clinical experience have more fully verified them. The disputed questions in regard to tuberculosis are not a few, and this one of human immunization to the disease may yet take its place among the more important ones like Koch's announcement of the non-intertransmission of bovine and human tuberculosis. If Maragliano is right in his assertion that the ingestion of milk and flesh of tuberculous animals produces immunity, a large proportion of the civilized population of the world must have acquired it by this time. Moreover, if a single attack of surgical tuberculosis produces immunity against the disease in all its forms, the number of immune must also, for this reason, be very large. It has been an accepted belief, based on what are supposed to be clinical facts, that old tubercular foci might be revived, and that they are consequently a source of danger in those who possess them. Certain able pathologists declare that with careful examination nearly every autopsy will reveal some traces of former tuberculosis. This would indicate that while no one was originally immune, everybody had a chance and ought to become so, by action of tuberculous attacks, if Maragliano's theory is correct. On the whole, it seems to us worth while to continue to believe that while a certain degree of immunity is probable, and while there may be a certain basis of fact for Professor Maragliano's theories, yet it will not do to accept them too freely or attempt to make them universally applicable.

PRELIMINARY EDUCATION FOR NURSES ENTERING TRAINING SCHOOLS.

Of the utility of the trained nurse there is no longer any ground for discussion. From having originally been

1. THE JOURNAL A. M. A., July 4, p. 67.
2. Medical News, July 4.

a luxury, to be availed of only by the wealthy few, she has become an every-day necessity, whose services are in constant demand among all classes of the community. In the process of evolution, the requirements of a good nurse have been gradually increased, and for the fulfillment of these the courses of study have necessarily been lengthened, and the character of instruction has been correspondingly modified. Training in the mere practice of nursing can no longer be considered sufficient, but a thorough grounding in the principles of the work has come to be looked on as an important prerequisite. Like the medical student, so the pupil-nurse should come equipped for her pursuit with special as well as general educational qualifications. A plea upon these lines has recently been made by Dr. Francis P. Denny,[1] and to meet the present need he lays down the following urgent requirements: 1. Leisure for study. 2. Instruction in the principles of nursing before beginning practical work. 3. Instruction by those especially fitted to teach. 4. Improved methods of instruction. That this need has been appreciated, in part at least, by others, and that steps have already been taken to provide the remedy is shown by the announcement of the Drexel Institute of Philadelphia for 1903-04 that at the solicitation of Dr. S. Weir Mitchell and the superintendents of the leading nurses' training schools of Philadelphia, the Drexel Institute has undertaken to organize a preparatory course of instruction for such training schools, including the subjects of anatomy and physiology, medical chemistry, materia medica, hygiene, bacteriology, domestic science and economics, as well as English language, vocal expression and physical training. The course occupies about thirty-six weeks, and is divided into two terms. Certificates will be issued to those who complete the full course and pass the required examination. It is possible that work of a like character has been undertaken elsewhere, but it seems worth while to make a record of the beginning of a movement whose influence is likely to be most useful and far-reaching. Further, the experience gained from this work may serve as a guide to others engaged in other places in similar work. It is fitting that grateful acknowledgment be made of the part taken in the movement by Dr. S. Weir Mitchell, who has always exhibited the greatest interest in nursing and nurses, and who has in many ways done so much for the uplifting of his profession.

Medical News.

ILLINOIS.

Personal.—Dr. and Mrs. Jacob Schenck, Mount Carmel, started July 4 for a four months' trip abroad.——Dr. Edward H. Thomas, Augusta, has resigned as trustee for the Illinois Hospital for the Incurable Insane.

Bartonville Cottage Contracts Let.—The board of trustees of the Illinois Hospital for the Incurable Insane, Bartonville, has awarded the contract for the erection of eight cottages to a Peoria contractor whose bid was $23,000 higher than the lowest bid made.

Hospital Additions Delayed.—The buildings which the Cook County Board of Commissioners propose erecting this summer at the County Hospital and the Dunning institutions have been delayed because the commissioners can find no purchaser for bonds at 3½ per cent.

Cornerstone Laid.—The cornerstone of Logan Hall, a building to be used for school rooms, gymnasium and dormitories for children under 10 years of age, was laid at the Beverly Farm Home and School for Nervous and Backward Children, Godfrey, to-day. The building will cost about $5,000, and will increase the capacity of the institution to 50.

Chicago.

A Polylingual Medical Dictionary Under Way.—Dr. Karl von Klein of Chicago is compiling a medical dictionary which aims to include all medical terms in every language.

Personal.—Dr. E. C. Dudley has been re-appointed a member of the board of education.——Dr. Albert C. Eyclesheimer, assistant to the chair of anatomy at the University of Chicago, has resigned to accept the professorship of anatomy in the University of St. Louis.

Illinois Medical College Changes.—Drs. J. F. Presnell, late surgeon U. S. V., and Frank Byrnes, have been elected junior professors of surgery. Dr. William F. Waugh has severed his connection with the college. The college has completed its new buildings, one of which is devoted to anatomical laboratories and the other is to be used as a training school for nurses.

Same Mortality.—The total of 563 deaths recorded by the bureau of vital statistics for the week ended July 11 was precisely the same as that of the previous week. Among these were 26 from sunstroke, and, as other direct results of high temperature, an increase of 38 deaths from the acute intestinal diseases, "convulsions" and the nervous diseases. Only 7 deaths were reported from typhoid fever, as compared with 11 during the week before.

MARYLAND.

Bequests.—By her will the late Mrs. Harriet Lane Johnston, Baltimore, bequeathed $90,000 for three free scholarships for the Johns Hopkins University, $1,500 to the National Homeopathic Hospital, $2,000 to the Church Home and Infirmary, and a reversionary amount for the Home for Invalid Children.

Personal.—Dr. John T. King sailed for Antwerp, July 11.——Dr. Joseph T. Hering of Westminster has been commissioned assistant surgeon of the First Maryland Regiment, now in camp at Belair.——Drs. Clinton Cushing of Washington, J. C. Jones of St. Louis, E. P. Quain of Bismarck, N. D., sailed from Baltimore for Bremen, July 8.

Contracts Let.—The contract for the erection of the new building for epileptic patients at the State Hospital for the Insane, No. 2, Sykesville, Md., has been awarded at $25,590. It will be of two stories, and of brick and terra cotta, 200 feet long, 50 feet wide in the center, and 25 feet wide in each wing. There will be accommodations for 100 persons, and 12 private rooms. The digging of the foundation has already been nearly completed, largely the work of the patients. The hospital is so crowded that the workshop has to be used for some patients.

Chair of History of Medicine.—A professorship of the history of medicine has been instituted at the University of Maryland School of Medicine. This is the first instance in which there has been a full professorship to this branch in any American school or university, although lectures have been delivered on it at a few institutions. The Johns Hopkins Medical School has a society specially devoted to it, and a small number of lectures are delivered there annually by Dr. John S. Billings. Some lectures are also delivered in Albany, St. Louis and Buffalo.

NEW YORK.

Bequest to Hospital.—The Buffalo General Hospital will become the recipient of $100,000 by the will of Mrs. Agnes Ethel Tracy.

State Examinations.—The June state examination for medical license, at Syracuse, was taken by about one hundred candidates.

Buffalo Personals.—Dr. Roswell Park, who has been ill with erysipelas, is much improved.——Dr. Marcel Hartwig is ill and confined to his home.——Dr. F. Park Lewis has been appointed chairman of the commission to investigate the condition of the adult blind in the state of New York.

Over Seas.—Dr. Lawrence Hendee, Ithaca, sailed, July 7, for Europe, where he will spend a year in study.——Dr. Montgomery A. Crockett, Buffalo, is spending three months in Hamburg, studying general surgery.——Dr. Frank A. Carr, Buffalo, has returned from abroad.——Dr. James W. Charters, Buffalo, recently sailed for a tour in Europe.

1. Boston Medical and Surgical Reporter, June 18, 1903, p. 657; see THE JOURNAL for July 4, 1903, ¶12, p. 56.

New York City.

A Large Estate.—Dr. Christopher M. Bell, who died in Baden Baden last year, left an estate of $2,667,000, all in personal property, according to the official appraisal just completed.

Convalescent Hospital.—On July 1 the Commissioner of Charities opened a hospital for convalescents on the north end of Blackwell's Island. There are at present accommodations for 40 men and 30 women, which will eventually be increased to 70 and 60 respectively. Ordinarily the patients will not be kept longer than three weeks.

Vital Statistics.—For the first six months of 1903 there were reported 34,855 deaths, as against 35,491 for the same period last year, giving a death rate this year of 18.67 per 1,000 as compared with a rate of 19.54 for the first six months of 1902. There is an increase of 6,000 in the number of reported births for this period, which is probably to be explained by the more strict enforcement of the law requiring the reporting of births by midwives and physicians.

OHIO.

Many Pass Examiners.—At the examination recently held, 85 applicants passed.

Smallpox in Jail.—Smallpox is reported to have developed among thirteen prisoners in the Mercer County jail.

College Consolidation.—The Miami and Laura-Memorial Woman's Medical colleges of Cincinnati have consolidated.

To Raise Curriculum.—The State Board of Medical Registration and Examination on July 8 assigned the work of deciding on a curriculum for medical schools in Ohio to a committee, consisting of Drs. Edward J. Wilson, Columbus; August Ravogli, Cincinnati; Harris H. Baxter, Cleveland, and Leo F. Towers, Toledo.

Physicians Injured.—Drs. Schuyler S. Tuttle and Richard J. Morgan, Van Wert, while journeying to Indianapolis in an automobile, ran into an open bridge and fell fifteen feet. Dr. Morgan sustained a fracture of the left thigh and patella, and of the right leg at the ankle. Dr. Tuttle fell on his head, producing a concussion of the brain from which he will recover.

Board of Appeals.—The board of appeals from decisions of the State Board of Medical Examination and Registration has sustained the decision of the board in revoking the license of Dr. Norman M. Geer, Cleveland, for gross immorality, and has reversed the decision in the matter of the revocation of the certificate of Dr. Charles F. Cookes, Columbus, charged with having performed a criminal operation, but never brought to trial.

PENNSYLVANIA.

Hospital Opens.—The Shope Hospital, Harrisburg, was formally opened July 2.

Many Candidates.—In the last week in June, 391 candidates took examinations for licenses to practice medicine, 246 in Philadelphia and 145 in Pittsburg.

Frankford Hospital Opened.—Frankford Hospital was formally opened July 4. Two physicians will be in constant residence, and, for the time being, three nurses.

Personal.—General orders announce the appointment of Dr. Sarden McClure of Philadelphia as assistant surgeon of the First Regiment, N. G., P.——The governor has appointed as a member of the State Board of Health, Dr. Charles E. Harvey, Philadelphia; as a member of the State Quarantine Board, Dr. J. L. Forwood, Chester.

Sanatorium Settlement.—Dr. J. T. Rothrock, state forestry commissioner, has contracted for the erection, on the state reservation near Waynesboro, of an assembly hall and six cottages at the White Pine Sanatorium which the state has established for tuberculosis. It is the purpose to establish a complete sanatorium settlement.

To Test Eyes.—Henry Phipps, Jr., has sent $350 to the First Ward Manual Training School, Allegheny, with a suggestion that the money be used in the examination of the eyes of the school children. He will add to his contribution a sufficient amount to secure treatment and the procuring of glasses for those who are found to need them.

Tour of Inspection.—On July 11 Governor Pennypacker, in company with state and city officials, including representatives of the state quarantine and state and city health boards, made, on a tug boat, an inspection of the Delaware River water front and of the Marcus Hook Quarantine Station. Of the party were Dr. R. A. Cleeman, president of the State Quarantine Board; Dr. Benjamin Lee, secretary of the State Board of Health; Dr. J. L. Forwood, member of the board, and City Health Officer Charles H. Heustis. The visitors were entertained at luncheon by Quarantine Physician Henry D. Heller.

Philadelphia.

Preparatory Course for Nurses.—The Drexel Institute of Art, Science and Industry, Philadelphia, has instituted a department for the preparatory instruction of nurses.

Personal.—Dr. Richard M. Pearce has been made adjunct professor of pathology and bacteriology in Albany Medical College and director of the Bender Hygiene Laboratory, vice Dr. George Blumer.——Drs. Charles B. Penrose and George A. Piersol have been appointed members of the Board of Health, vice two laymen, resigned.——Dr. Andrew J. Downes has returned from Europe.

Fourth of July Tetanus.—For the week following the Fourth of July, at least five died of tetanus, and others were reported in a critical condition from the disease. Three of the deaths were directly traceable to injury by toy pistols. The dealers who sold the pistols have been summoned to answer in court; an act of the assembly makes it a misdemeanor to sell pistols to children under fourteen.

Appointed to Professorship.—Allen J. Smith, professor of pathology and dean of the medical department of the University of Texas, has been elected to the chair of pathology in the University of Pennsylvania. The latter was made vacant by the resignation of Dr. Simon Flexner, who takes charge of the Rockefeller Institute in New York City. Dr. Smith was graduated from the University of Pennsylvania in 1886. He was for several years demonstrator of pathology in his alma mater.

Pure Food Crusade.—The crusade against impure foodstuffs made by Food Commissioner Warren, is bearing fruit. At the invitation of the Philadelphia Pork Packers' Association the food commissioner and Secretary of the Board of Agriculture Critchfield recently met representatives of the association to consider the question of impure lard. Several dealers have lately been fined for dealing in spurious lard. The packers promised the aid of their association to the commission and board of agriculture.

A Cold June.—The month of June was the coldest in Philadelphia ever recorded by the weather bureau. The average temperature was one and a half degrees lower than the coldest previous June, 1881. The minimum temperature was 51 degrees, the maximum 84 degrees. In marked contrast have been the conditions for the week of July ending the 11th. Throughout much of the days the thermometer has ranged in the 90's and the humidity has been great. As a result, there have been many cases of heat prostration, not a few proving fatal.

Improvement Hoped For.—Dr. Martin, the new director of the Department of Health and Charities, by his activity since assuming the duties of the office, has inspired a belief that the hygienic and sanitary affairs of the city are to have a much-needed improvement. Among essential innovations Dr. Martin advocates a modern system for the disposal of sewage, probably its evaporation and conversion into fertilizer; also the systematic medical inspection and examination of public school children and of public school buildings. This may be done by the regular medical inspectors of the bureau of health, or by a special corps to be appointed.

Bequests.—Among bequests awarded in adjudicating the estate of the late Owen Lamb, are the following: St. Joseph's Hospital, $500; St. Mary's Hospital, $15,734.——The following are some of the many charitable bequests made by the late Mary M. Johnson: Pennsylvania Hospital; Insane Department of Pennsylvania Hospital, for free beds; Asylum for the Relief of Persons Deprived of the Use of Their Reason; University Hospital; and Woman's Hospital, all of Philadelphia, $10,000 each; Pennsylvania Training School for Feeble-Minded Children, and Orthopedic Hospital, $5,000 each; Philadelphia Home for Incurables, $2,000, and Children's Seashore House, Atlantic City, $5,000.

Hospital Plans Stopped.—Progress in the plans for an institution in the Forty-second ward for a city almshouse and hospital for the insane, has been stopped by the department of health. An ordinance passed in the recent administration provided for the removal of this institution to said site, near the House of Correction, the land there owned by the city being about 100 available acres. The present officials regard the site as being entirely too small; they favor the separation of the almshouse from the immediate vicinity of the hospital for the

insane, and the provision of large tracts of land for each institution whereby both may be largely self-sustaining, and where the insane may be treated in accord with modern methods. Plans are for the present held in abeyance.

Smallpox Persists.—Not only does smallpox persist in the city, but despite the warm weather and the efforts of the health authorities, seems even on the increase. For the week ended July 11, 39 new cases and 10 deaths were reported, the largest number for many weeks. The condition is so serious as to lead the department of health to renewed efforts to stamp out the disease. Vaccination, supplemented by fumigation and quarantine, is considered the one weapon of attack. Letters have been sent by the department to hospital officials asking them to refuse to admit patients who have not been successfully vaccinated within five years. Letters have also been sent to employers, asking a similar requirement of their employes, the department offering to send physicians to do free vaccination. The public has thus far failed to be aroused to a sense of the gravity of the situation, or of the necessity for general vaccination. A sentiment is gaining for compulsory vaccination. A corps of physicians have been doing house-to-house vaccination in the infected district. House inspection is being done, nuisances are to be abated, streets and alleys flushed, and garbage removed.

TENNESSEE.

Addition to Hospital.—The Presbyterian Home Hospital, Memphis, will erect an addition to the present building, to cost $12,000.

State Medical Directory.—Dr. T. J. Happel, Trenton, secretary of the State Board of Medical Examiners, is preparing a directory of all legally qualified physicians in Tennessee.

Personal.—Dr. William B. Malone, Memphis, has been appointed major and surgeon, and Dr. I. Lucius McGhee, Memphis, captain and assistant surgeon in the National Guard and assigned to the Second Infantry.——Dr. Samuel S. Briggs has been elected professor of anatomy, and Dr. George C. Savage, secretary of the faculty of the medical department of Vanderbilt University, Nashville.

State Anatomical Board Appointed.—The governor has appointed a board consisting of Drs. Samuel S. Briggs, Paul F. Eve, John S. Cain, Richard A. Barr, William G. Ewing of Nashville; Dr. William B. Rogers, Memphis; Dr. Walter S. Nash, Knoxville, and Dr. Edward A. Cobleigh, Chattanooga, to receive and dispose of the unclaimed bodies of persons who die in charitable and penal institutions in cities of over 40,000 population. The appointments are made on recommendation of the various colleges.

CANADA.

Brandon General Hospital.—The Brandon (Manitoba) General Hospital is to be increased by an addition which will cost $18,000 and accommodate 32 beds.

St. John, N. B., Vital Statistics.—For the first six months of 1903 there were 569 births, 457 deaths and 207 marriages in the city and county of St. John, N. B.

Royal Jubilee Hospital, Victoria, B.C.—The total number of in-patients treated during the past year in the above institution was 784; the total number of out-patients 163, as against last year, in-patients, 782; out-patients, 122. The cost of maintenance during the year was $31,831.17, while the daily cost per patient was $1.80.

New Hospital for Vancouver.—The sum of $30,000 has been subscribed for a new general hospital by the citizens of Vancouver, B. C. The city has contributed $20,000, and as a result the provincial government now announces that it will contribute $20,000 additional. A building will be erected capable of accommodating 100 patients, and so arranged that it can be enlarged at any time to provide for at least 300 patients.

Prince Edward Island Hospital.—The annual report of the Prince Edward Island Hospital shows that there were admitted during the past year to that institution 243 patients, 7 more than for the previous year. The paying patients numbered 165. The medical cases were 70, surgical 173, and 131 underwent operation. There were 183 patients discharged cured, while the deaths numbered 8, as compared with 2 during the previous year. There remained in the hospital on May 23, 16 patients. The out-patients numbered 38.

Judgment in an Eddyite Case.—The practice of Eddyism in Ontario has received a severe set-back at the hands of the Ontario Court of Appeals in the judgment delivered by that court in the case of the King against a citizen of Toronto who permitted his boy, aged 16, to die of diphtheria without providing him with necessary medical treatment. At the first trial the jury had found the prisoner guilty of manslaughter and the defendant's counsel had taken the case to the Court of Appeals. The decision of the Court of Appeals states clearly that they think that the learned judge at the first trial did properly charge the jury that the term "necessaries of life," as appears in the criminal code, includes medicine and medical treatment.

Anti-Vaccination Bill Killed.—One of the members of the Ontario legislature had before that body during the past session an anti-vaccination bill, the object of which was to remove the compulsory clause of the Public Health Act. In aid of this the legislator presented a petition signed by 1271 residents of Galt, Ont., which town had just passed through a smallpox epidemic, in favor of the bill. Dr. Reaume, a member of the legislature from Western Ontario, strongly opposed this measure and said that he had been vaccinating for 20 years, and had yet to see the first evil result. As only one or two members at the outside were in favor of the legislation the bill never saw more than its second reading.

Montreal Anti-Tuberculosis League.—A meeting of the investigation committee was held last week, presided over by Dr. Roddick, M.P. Dr. Harding, Montreal, was appointed to act as permanent secretary to the committee. A number of physicians representing the different departments of the various city hospitals and dispensaries were present and discussed with the committee the co-operation of these institutions with the league. Each and all reported that the several hospitals and dispensaries of Montreal were willing and glad to co-operate with the league in reporting cases of consumption that came under their notice. Arrangements were made by which each hospital will fully report the tuberculous cases which come under its care. This will greatly aid the league in its efforts to obtain information and give it greater opportunities in trying to stamp out tuberculosis in that city.

FOREIGN.

Damages for Venereal Infection.—The Munich courts have condemned to five months' imprisonment a postoffice employe who had established intimate intercourse with a chambermaid of good character ("ein unbescholtenes Zimmermädchen"), although he knew that he was suffering from an uncured venereal disease.

Sanatoria for the Madeira Islands.—Our German exchanges announce that the Portuguese government has granted permission to the Prince von Hohenlohe to erect the sanatoria on the Madeira islands which he has been projecting. Work will be begun at once and the government will grant certain concessions and privileges in order that the buildings may have the most favorable location and surroundings.

Organization of the Profession in Switzerland.—There is rejoicing in Switzerland over the realization of the long cherished hope of united organization of the medical profession. The general meeting held at Lausanne, June 12-14, was attended by 350 members and delegates from all parts of the country, instead of, as heretofore, each part of the country holding its separate meeting. Besides the usual excursions and clinics by prominent visitors, a number of scientific articles were read, among them one by Kocher on "Treatment of Goiter"; by His on "Articular Rheumatism," and by Bard on the "Importance of Laboratory Research for Practical Medicine."

Recent Decisions of the German Medical Court of Honor.—Among the recent decisions is one that designates as unworthy of a physician the announcement of a new remedy according to the mode of advertising addressed to the lay public, even of a remedy supposed to be of great benefit for the welfare of mankind. The court has also recently affirmed that every physician has a right to establish himself in any place he pleases. The fact that the medical practice at the place is only sufficient to support one physician does not affect this right from the standpoint of the official court of honor. In still another decision the court denounced depreciatory criticism of the testimony of another physician in a medicolegal affair. Going beyond the limits of criticism of the matter under discussion and rebuttal of the testimony of the experts on the other side, is likewise contrary to medical professional honor.

Suits Against Charlatans in Germany.—The drop curtain of the "Central Theater" in a large German City has served as the advertising medium for the charlatan Westphal, who announced on the curtain that he guaranteed a cure for the so-called incurable diseases. In the lay press he has also been publishing that a local magistrate had endorsed from the bench the value of his curative methods. The latter had merely

stated in a previous suit that the defendant might possibly have accomplished a cure in certain isolated cases, but that his claim to cure all diseases was preposterous. Westphal sought to evade the law also by arguing that the use of the term "so-called" incurable did not include the actually incurable. He was condemned to a fine of $50 for the use of the magistrate's name. Another charlatan has been recently condemned to six weeks in prison for personal injury from his practices in a certain case.

LONDON LETTER.

Acute Recurrent Hydronephrosis.

At the Clinical Society of Manchester Dr. Arnold W. W. Lea read a paper based on four cases treated by operation. The condition is marked by recurrent attacks of acute abdominal pain with severe constitutional disturbance, and is associated with rapid swelling of the kidney and temporary hydronephrosis. It may be found with mobile kidney, but extreme mobility may exist without any hydronephrosis. Mr. Bruce Clarke in 1893 described this condition as "acute renal dislocation," the kidney slipping down below the costal margin. In the cases described by Dr. Lea reduction of the kidney, even under an anesthetic, was impossible owing to the greatly increased size of the organ. The cause of the condition was temporary ureteral obstruction. Slight degrees of ureteral obstruction are common in mobile kidney, producing some hydronephrosis, but in the acute cases an additional element is introduced, namely, sudden kinking or torsion of the ureter. Valvular folds are frequently in the upper part of the ureter near the renal pelvis. Sometimes also strictures occur from various causes. Reference was made to an interesting paper by Bary of Paris, who had examined the ureter and renal pelvis of a large number of newly-born infants. Among 68 cases only 15 were found in which the ureter was absolutely normal; valvular folds, narrowings, and kinking or torsion to some extent were present in 31 cases. These arose in the wall of the ureter itself. The pelvis of the kidney also showed great variation in size and shape and the angle of insertion of the ureter might be vertical or horizontal. The form most liable to lead to hydronephrosis is a voluminous renal pelvis, with the ureter entering at an acute angle. Sudden strain or effort may then produce obstruction of the ureter and hydronephrosis. Other factors, such as congenital stenosis, valves, and twists, also conduce to the production of recurrent hydronephrosis, so that this condition is largely dependent on the disposition of the ureter and renal pelvis. In these cases slight descent of the kidney, not recognizable clinically, may lead to acute ureteral obstruction. The symptoms might be very severe. In one case the attack came on at frequent intervals without obvious cause, and was accompanied by intestinal obstruction due to displacement of or traction on the colon. A distinct tendency exists for the attack to occur just before the menstrual period. This occurred in two cases and may suggest a pelvic cause for the symptoms. The attack may last 3 to 5 days, and then within a few hours the kidney may return to the normal size and all the symptoms disappear. In the intervals the patients may be well, but they are usually neurasthenic and have constant aching in the loin. The diagnosis is easy if a definite tumor can be felt, but in the earlier stages of ureteral obstruction with dilation of the pelvis the symptoms may be very severe, even in the absence of any definite tumor. The treatment must be mainly surgical; palliative measures rarely effect a cure. The kidney must be exposed. In the great majority of cases nephrorrhaphy effects a permanent cure. In slight cases it is unnecessary to drain the renal pelvis; if, however, the kidney is hydronephrotic, the pelvis must be incised and a careful examination made of the upper end of the ureter. If no obstruction is found, the pelvis may be sutured and the kidney fixed. Nephrorrhaphy is carried out by Dr. Lea in all the cases; in three the pelvis of the kidney was opened, and in one it was thought advisable to drain for a few days. In each case a permanent cure was obtained. It is important not to delay operation too long, as otherwise the kidney may be irrefrievably damaged. There is also a great tendency to development of pyonephrosis from ascending from the bladder, or possibly from adhesions forming between the colon and the perirenal tissues.

Trypanosomiasis in Africa.

Drs. J. E. Dutton and J. L. Todd of the trypanosoma expedition of the Liverpool School of Tropical Medicine have just returned to England from Senegal. They especially devoted their time to research work, with a view to determine the frequency, incidence and distribution of "trypanosomiasis" in the territory of the Gambia and the adjoining French colonies. They found that the disease occurs frequently in both Europeans and natives, and that it is distributed from the sea to the Upper Gambia. The disease is caused by a parasite, trypanosoma, very similar to that which engenders the "tse-tse fly disease." Besides the human disease in the Gambia there is, in addition, a species of "tse-tse fly disease" which attacks horses, and is the chief cause of the great mortality of horses in that country. The expedition reports a very important fact with regard to the health of the Gambia, namely, that the principal medical officer of that colony had officially announced that since Sir George Denton and his medical staff have organized mosquito destruction and similar sanitary measures in Bathurst there has been a most marked reduction in diseases of the malaria type, both in Europeans and natives.

The Care of Children's Teeth.

At the annual meetings of the British Dental Association, the president, Mr. Walter Harrison, in his opening address. said that he deplored the apathy shown in the dental condition of the young. There was anxiety on the part of parents of the upper and middle classes regarding the state of their children's teeth and the principals of schools also showed that they were not indifferent in this respect; but public bodies did not realize how absolutely necessary to the health was a perfect set of teeth. The association was in a position forcibly to demonstrate the necessity of a royal commission to inquire into the condition of the teeth of poor children.

Death of Mr. William Cadge.

One of the most famous of the provincial surgeons of England has passed away at the advanced age of 81, "Cadge of Norwich" as he was called throughout the medical world. His active work had long been finished and he was simply a connecting link with the past. In 1845 he passed his examination for membership of the College of Surgeons, and became Liston's assistant, with whom he worked until his death in 1847. He next became demonstrator of anatomy in University College and contributed the article "The Surgical Anatomy of the Head and Neck and Upper Limbs" to "Morton's Surgical Anatomy." In 1848 he obtained the Fellowship of the College of Surgeons, and in 1850 was appointed assistant surgeon to University College Hospital. In 1852 he returned to Norwich, where he had received his earliest medical education, and was appointed assistant surgeon to the Norfolk and Norwich Hospital. The great prevalence of urinary calculus in the district gave him an almost unique experience of the condition which he put to such excellent use as to establish a reputation throughout the world. He was not only a most expert lithotomist but a scientific investigator of the first rank. He attributed the striking absence of stone in the children of the well-to-do to the fact that they drank milk. On the other hand, he blamed the strong, sweet, new beer which the Norfolk peasants drink liberally. He was disposed to believe that the hard water of Norfolk favored the production of stone. He had great success with lateral lithotomy, and consequently valued the operation highly. In his Hunterian lectures delivered at the Royal College of Surgeons in 1886 he stated that he had performed lithotomy 169 times with 29 deaths. In the 29 fatal cases the average age was 60 and average weight of the stone 2 oz. For large stones he preferred the suprapubic method, especially for the hard uric acid stones of his native country. Though an experienced and expert lithotritist he would not admit the claim of many surgeons that lithotomy should be abandoned. In 1880 he was elected member of the council of the College of Surgeons, a post which he held for 16 years. He presented two munificent donations to his hospital, $50,000 in 1889, and the same sum again in 1899. He was married to a sister of the late Sir Richard Quain, who predeceased him and left no children.

Correspondence.

The Demise of the Philadelphia Medical Journal.

PHILADELPHIA, July 11, 1903.

To the Editor:—In your issue for July 11 there appears a letter from Dr. George M. Gould in which, as is usual with him, he undertakes to point morals. As a pointer of morals Dr. Gould has acquired that facility which comes from a contemplation of the sins of others rather than from a serious inspection of his own faults; and it is, therefore, wholesome and right that one of his friends should hold the mirror up to his gaze. As a

friend of the editor of *American Medicine*, and as the one who took the editorial chair after his enforced retirement from the *Philadelphia Medical Journal*, I greatly regret that Dr. Gould should have missed seeing the true significance in the passing of the latter journal while the former is still permitted to exist.

Those who are perfectly familiar with the inside history of the *Philadelphia Medical Journal* can trace its misfortunes to two main causes which existed at its very organization: 1. The selection of Dr. Gould for editor. 2. The permitting the stock to fall into the control of a newspaper publisher who failed to agree with Dr. Gould and forced his retirement. Between this upper and nether millstone the journal came near being torn to pieces, and it was only by the efforts of some physicians and laymen of the highest character that the journal was temporarily saved. It is a mistake on Dr. Gould's part, however, to suppose that the differences between himself and everyone else were entirely ethical, and that he was in the right and everyone else was in the wrong. The differences were not entirely ethical, but were largely temperamental and were such as grew out of the fact that some otherwise very worthy men were not able to get along with Dr. Gould. That "commercialism"—about which the editor of *American Medicine* talks with the ease of one perfectly familiar with it—was not the only or chief cause of difference between Dr. Gould and the majority stockholder, is amply proved by the fact that no sooner did he establish *American Medicine* than he adopted a commercial policy more flagrantly offensive to the ethical sense of the medical profession than was ever followed by the *Philadelphia Medical Journal*. In this respect, indeed, he proceeded to out-herod Herod.

The truth of this assertion is proved by a glance at the advertising pages of *American Medicine*. Proprietary nostrums are admitted to an extent that shows the dependence of the journal on its advertisers, and, worse than all, a special advertising department has been maintained in which Dr. Gould publishes puff articles of proprietary medicines printed in such a way as to look exactly like original articles. I know of no reputable journal in America that does such a thing as that. Neither does he disguise that he is responsible for the business as well as the editorial conduct of his journal. These things being so, if Dr. Gould has the slightest sense of humor, he must be getting more fun out of the situation than are some of his stockholders. According to an old monkish legend St. Denis, after he was beheaded, went about carrying his head in his hands. Dr. Gould emulates the example of this holy man. Ever since he was decapitated he has gone about exhibiting his disjointed head as though it were the casket of all the virtues. So far as learned at this writing, however, he has not yet paid 5 per cent. on his stock.

When I assumed editorial charge of the *Philadelphia Medical Journal* I found that all the virtues had not departed with the enforced retirement of Dr. Gould. On the board of trustees were such men as Dr. James Tyson, Dr. J. C. Wilson, Dr. William Thomson, Dr. E. Sajous, Dr. J. B. Roberts, Dr. J. H. Musser, Dr. H. Leffmann, Dr. W. Pepper, Jr., Dr. J. Neff, and Dr. Coplin; while among the friends of and contributors to the journal during the time I edited it, were such men as Professor Keen, Professor Osler, Professor Welch, Professor J. Wm. White, Dr. Louis Starr, Dr. Mills, Dr. Dercum, Dr. Sinkler, Dr. J. B. Deaver, Dr. Joseph Price, Dr. de Schweinitz, Dr. Randall, Dr. E. P. Davis, Dr. F. P. Henry, Dr. Frazier (dean of the University of Pennsylvania), Dr. Edward Martin, Drs. Dana, Starr, Sachs and Spitzka of New York, Dr. Putnam of Boston, and Dr. Jelliffe, editor of the *Medical News*. Surely among these names are to be found the names of some men who can be credited with an adherence to high ethical, literary and scientific standards!

The *Philadelphia Medical Journal* went out of existence "in the city of its birth" because the members of the editorial staff found that they could not control its policy against a small coterie of majority stockholders, and because they preferred to see it die rather than pursue a commercial policy, such as now characterizes Dr. Gould's journal. It is because Dr. Gould has failed to see the true moral of this tale, or the true handwriting on the wall, that I have thought it worth while to call his and the world's attention to it.

JAMES HENDRIE LLOYD.

Queries and Minor Notes.

PORTA'S EXPERIMENTAL RESEARCH ON LIGATURE OF THE ARTERIES.

OGDEN, UTAH, July 7, 1903.

To the Editor:—Will you kindly inform me through THE JOURNAL, the nature and results of Porta's experiments on ligation of the aorta? I find references to them in several works, but none of them give any details. H. B. F.

ANS.—One of the gems in medical reference libraries is a handsome folio published in Italian at Milan in 1845 by L. Porta,* professor of surgery at Pavia. It contains 439 pages with a number of plates. In it he reports 600 experiments on 270 animals, including rabbits, dogs, sheep, goats, horses, asses and beeves, but principally on dogs, as he considered their physical organization as resembling most closely that of man. He reports the details of 113 experiments, undertaken to determine what becomes of a ligature left on an artery, and what changes are induced in the artery and in the circulation by ligature, single, double or over a cylinder, or torsion of an artery. He also reviews 600 operations undertaken on man at that date in which an artery had been ligated or twisted, studying closer the 49 cases in which gangrene occurred and the 30 deaths out of the 75 cases with hemorrhage. In his experiments he ligated the carotid, subclavian, brachial, femoral and abdominal aorta. Out of 60 animals on whom the latter artery was ligated, 7 survived, and Pirogoff had 2 survive out of 17. He speaks a good word for torsion of the artery in place of ligation for the treatment of wounds of medium sized arteries. He applied it in 18 clinical cases, generally after amputations, etc., on the basis of the results of 60 experiments on large animals in which hemorrhage occurred in only 11. He found it simple, easy and certain for the majority of his cases of wounds of the carotid, subclavian and femoral arteries, twisting them six or seven times on their axis.

GRATUITOUS SERVICES TO A PHYSICIAN.

NEW YORK, N. Y., July 9, 1903.

To the Editor:—Will you kindly advise me in this matter? Dr. A. is suddenly taken very ill, so that he can not choose his medical aid. His family under great nervous strain call in the first physician found at home, Dr. B., who does not know Dr. A. personally. He treats Dr. A., and makes two calls altogether. A few days later Dr. B. sends a bill "for services rendered to son" to Dr. A.'s father. How is Dr. A. to behave in the case? L. H.

ANS.—Article II, Chapter 2, of the Principles of Medical Ethics of the American Medical Association says:

"All practicing physicians and their immediate family dependents are entitled to the gratuitous services of any one or more of the physicians residing near them."

Were we in Dr. A.'s place we should first pay the bill rendered by Dr. B. and then send him a copy of the Principles of Medical Ethics of the American Medical Association with the above paragraph marked in blue pencil.

SOLUTION OF NITRATE OF SILVER.

TOLEDO, OHIO, July 3, 1903.

To the Editor:—I noticed in THE JOURNAL an editorial on Fourth of July injuries in which bichlorid, 1 to 1000, is advised as a cleansing solution. Pepper's Practice says silver nitrate, 1 to 1000, destroys germs in five minutes. Can you tell me whether this silver solution is generally looked on as efficient? J. L. T.

ANS.—A solution of nitrate of silver, 1 to 1000, is an efficient germicide, but not applicable as a general irrigating fluid.

Miscellany.

Removal of Birth-Marks.—Dr. L. L. McArthur described, at a meeting of the Chicago Surgical Society, a method which he believes to be new for the eradication of vascular blemishes of the integument. As the red color of these marks is due to capillary dilatation, it is necessary to obliterate the capillaries. To do this he conceived the idea that if, on a plane horizontal to the surface on which this pigmented area rested, a section was made of the integument in such a way that the entire thickness of the integument would not be destroyed, but that the knife should pass through each capillary loop as it came

* Delle Alterazione Patologiche delle Arterie per la Legatura e la Torsione.

to the surface, he would then have integument still enough intact to prevent actual perforation of the same, with projection of the connective tissue beneath. After waiting for coagulation of the blood in these cut capillaries, a thin Thiersch graft was applied; all of these cut capillaries would then be obliterated, being plugged with blood-clot, which, becoming organized, would simply destroy the pigmented appearance of such a mark. Eighteen months ago a young woman presented herself with a very pronounced mark that extended over the forehead from the scalp to the eyebrow, including the eyebrow, the upper eyelid, and a portion of the malar prominence of the cheek. He adopted such a method as he described on a surface which had already received electrolysis and various other methods for the destruction of the vessels and color without avail, and succeeded in obtaining an excellent result. The patient was exhibited.

Education Preliminary to Medical Study.—The *Mississippi Medical Record* says this is a matter "of primary and paramount importance, and it is to be regretted that Dr. Billings did not emphasize the evils of the course pursued by many of our so-called reputable colleges even more forcibly. The reason the 'mortality rate' at examinations by our state boards is so high is easily accounted for when we find that fully one-half of the applicants are almost totally ignorant of the rudiments of English grammar and do not know the meaning of many of the simplest words of our ordinary language. We do not expect that the medical schools will ever require a college diploma as a requisite for entrance. It is not necessary, as many of our ablest practitioners are living witnesses. But it is pitiful in the extreme to see how far some of our schools descend in their eagerness to get patronage. Why can not we help? Most students, especially in our country districts, have preceptors and these gentlemen, despite the insinuation of a recent 'Fable' of Mr. Ade, do aid their students very materially in their choice of and preparation for their medical colleges. Can not these preceptors impress on their students the advisability of devoting their spare time to the acquirement of that general knowledge that will be of real benefit to them, not alone during the college course but throughout their entire lives, rather than to set them digging aimlessly into the primary branches and laboriously acquiring a few unimportant facts that they would take up 'by absorption' during their first course if their minds were better fitted to contain them?"

Medical Centenarians.—Picard writes an interesting historical sketch of this subject in the *Gazette Med. de Paris* for April 4 and 11, reviewing also the life insurance and other statistics in regard to "when and how physicians die," quoting extensively from THE JOURNAL. Hippocrates, he states, is said to have lived 104 years, and 140 is ascribed to Galen by one enthusiastic historian, but not by others. Three Arab physicians are cited as centenarians, and Picard has found records in France of four before Patenôtre, who died in 1709, aged 103. Poncy, who died at Paris in 1724, was born in 1623 and practiced to 100. Politiman is another French physician who lived into his second century—his biographer states to 140—and was in the habit of getting tipsy every evening, as also Dr. Espagno, who died at 112. A portrait of a Dr. P. Defournelle, inscribed 1690 to 1810, is preserved at Paris, but the first official record of a medical centenarian in France is Dr. A. Chaule, born in 1741, who lived to be 103, followed by Dr. Fau, also 103. Dr. Zalewski's death notice recorded at Bordeaux credits him with 111 years, and states that he was born in 1780, but no official record of his birth has been found. Dr. Bossy, who died at Havre in 1897 at the age of 104, was in such good health to the last that he made a trip to London three years before. His grandfather was 99 at the time of his death, and his father 108. The latter died at London in 1848 and had always enjoyed good health. Dr. Jean David of Montpellier celebrated his 102d birthday, February 10, 1903. He retired from active practice at 98. Picard has found four medical centenarians among the English members of the profession of the last century and five in this country. The latter are Dr. C. Smith, Cairo, Ill., and New York, who is said to have married at 123; Dr. D. Burke, Washington; Dr. H. Courtnay of Hancock; Dr. W. B. Sprague, and Dr. O. S. Taylor of Auburn, N. Y., concluding with Dr. C. Graham, whose centennial was celebrated by a banquet mentioned in THE JOURNAL in 1884, p. 549. Dr. Mavrogenis was a Greek physician, who attained the age of 100 in 1898, and a Swedish physician, Dr. Ivervex, is said to have invented an elixir which enabled him to live to 104. Only two Italian medical centenarians are mentioned and both died in the eighteenth century. A. Dr. O. Kownasky in Russia is said to have served in the Napoleon wars and died in 1887, aged 109. He was paralyzed for sixteen years before his death, but continued his practice to the last. It is said that he dictated a prescription a quarter of an hour before he died. In Spain Dr. F. Verdugo lived to be 105, practicing at Salamanca for eighty years, until his death in 1867. Another Spanish colleague was mentioned in 1875 as 105 years old, living in good health with a wife of 103. Dr. David, above mentioned, seems to be at present the dean of the profession the world around. Picard hopes to hear from others in regard to medical centenarians, as he would be glad to render his compilation as complete and accurate as possible. Communications addressed to him, M. L. Picard, care *Gazette Med. de Paris*, 93 boulevard St. Germain, VI, Paris, will be thankfully received. He cites his authorities in detail, with extracts.

Book Notices.

A TEXT-BOOK OF LEGAL MEDICINE AND TOXICOLOGY. Edited by Frederick Peterson, M.D., Chief of Clinic, Nervous Department of the College of Physicians and Surgeons, New York; and Walter S. Haines, M.D., Professor of Chemistry, Pharmacy and Toxicology, Rush Medical College, in Affiliation with the University of Chicago. Cloth. Pp. 750. Price, $5.00. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

This is the first volume of a system of legal medicine, rivaling, if not exceeding, in size the earlier one edited by Hamilton. Like the latter it is a composite production, and in this first volume we find the names of a number of well-known authors as contributors, such as Drs. Smith Ely Jelliffe, Ludvig Hektoen, Graeme M. Hamilton, Chalmers Da Costa and the late Dr. J. T. Eskridge, as well as the editors, whose well-known work in their departments has made them authorities. The articles are well written, as might be expected. The editors have made but little change in the work of their contributors, desiring them to retain the responsibility for their statements, a matter of some importance in medicolegal proceedings. They have followed the usual English standards of weights and measures throughout the work and the nomenclature and spelling of the U. S. Pharmacopeia. The volume covers the subject of expert evidence, postmortem examination, identity, signs of death, death from other causes, wounds, burns, railway injuries, medical jurisprudence of life and accident insurance, vision and audition in their medicolegal aspects, disorders of speech, inebriety, stigmata of degeneration, insanity, idiocy and mental perversion of sexual instinct. The contents of the succeeding volumes are given, which is a matter of convenience to the possessor of this volume. The work is illustrated wherever it seems necessary. The publishers have done their part, as usual, in an admirable manner. The book will fill a place in medicolegal literature, and, if we are not mistaken, will soon be recognized as a standard.

CANCER AND OTHER TUMORS OF THE STOMACH. By Samuel Fenwick, M.D., F.R.C.P., Consulting Physician to the London Hospital, and W. Soltau Fenwick, M.D. Lond., M.R.C.P., Senior Physician to the London Temperance Hospital. Cloth. Pp. 362. Price, $3.00. Philadelphia: P. Blakiston's Son & Co. 1903.

The major portion of this volume, as was to be expected, deals with cancer of the stomach. The work is almost entirely a statistical one. A large number of cases collected from various sources have been carefully analyzed and much interesting and useful data presented. The authors recognize three varieties of carcinoma of the stomach, namely, the spheroidal cell, including the hard or scirrhus and the soft or medullary; the cylindrical cell, or adenocarcinoma, and the colloid. The modern theories concerning the etiology of cancer are not mentioned, but this phase of the subject is handled, as are the others, in a statistical manner under the headings of Fre-

quency, Age, Sex, Geographical Distribution, Topography, Race, Heredity, Traumatism, etc. Some interesting facts are here recorded, but nothing that throws the least light on the cause of this great scourge. The authors do not favor exploration of the stomach through an abdominal incision as an aid to early diagnosis in suspected cases, but their reasoning in this regard is not sound, and until some better method of early diagnosis can be found, all hope of permanent relief must rest on more frequent and early exploration in suitable cases. The surgical treatment of cancer of the stomach occupies less than four pages, and merely touches on some of the indications for operation. The illustrations showing the gross anatomy of the disease as it affects the various portions of the stomach are very good.

THE PATHOLOGY AND DIFFERENTIAL DIAGNOSIS OF INFECTIOUS DISEASES OF ANIMALS. By Veranus Alva Moore, B.S., M.D., Professor of Comparative Pathology, Bacteriology and Meat Inspection, New York State Veterinary College, Cornell University, Ithaca, N. Y. With an Introduction by Daniel Elmer Salmon, D.V.M., Chief of the Bureau of Animal Industry, United States Department of Agriculture. Illustrated. Cloth. Pp. 380. Ithaca, N. Y.: Taylor & Carpenter. 1902.

While the average physician does not consider himself called on to study veterinary medicine, yet most country practitioners, and not a few city ones, will find some knowledge of the diseases of domestic animals of value to them in their practice. The present volume describes the leading disorders of most of the useful domestic animals, not only their symptoms, but their pathology, bacteriology, etc., and the volume forms a really valuable elementary treatise on the subject. When we consider the amount of money that is invested in animals and their usefulness, the part they play in the economy of our country, and especially the rural communities, the utility of such a book as this—lacking fuller treatises—to the physician can not but be manifest. As to its merits, the author, Dr. Moore, has long been known as one of the leading veterinarians of this country, and the fact that Professor Salmon, chief of the Bureau of Animal Industry of the United States Government, is ready to endorse it solely on his acquaintance with the author is a significant fact. The book is well gotten up and fully illustrated, the illustrations being well selected, and such as materially aid the text. The style is simple and clear, and the subject matter is treated interestingly. It is a work that should be welcomed, and have a wide circulation in the profession.

SURGICAL ANATOMY AND OPERATIVE SURGERY. For Students and Practitioners. By John J. McGrath, M.D., Professor of Surgical Anatomy and Operative Surgery at the New York Post-Graduate Medical School. Illustrated with 227 Illustrations, Including Colors and Half-tones. Cloth. Pp. xiv-559. Price, $4.00 net. Philadelphia: F. A. Davis Company. 1902.

In this volume the author has attempted to "combine in a practical manner the subjects of surgical anatomy and operative surgery." In attempting to cover both subjects much of importance has been omitted from each. The anatomy is often elementary and the description of operations stereotyped. One fails to find mention of much that is modern in operative work; for instance, the De Vilbiss rongeur or Gigli saw in head operations; Brophy's operation for cleft palate; Connell's principle of intestinal suture; perineal prostatectomy, etc. Indications for operation and points in favor of one method of operating over another in particular cases are not touched on. Some of the illustrations give erroneous ideas; for instance, Kraske's operation from the illustrations appears very simple and superficial, while on the contrary it is not only a difficult operation, but one in which the parts involved lie at considerable depth. As a guide to students taking the author's operative courses the work would be of value, but it would not fill a long-felt want with the practicing surgeon.

DISEASES OF THE PANCREAS AND THEIR SURGICAL TREATMENT. By A. W. Mayo Robson, F.R.C.S., Senior Surgeon, Leeds General Infirmary; and B. G. A. Moynihan, M.S. (Lond.), F.R.C.S., Assistant Surgeon, Leeds General Infirmary. 293 Pages, Illustrated. Cloth. Pp. 293. Price, $3.00 net. Philadelphia and London: W. B. Saunders & Co. 1902.

This volume is one of the most interesting and valuable monographs that has appeared during the past year. It deals with the surgical aspect of pancreatic diseases, and since the diseases of this gland have been studied more directly by the surgeon, much that is new has been learned, both in regard to the etiology and the treatment of the pathologic conditions of this heretofore somewhat obscure and rather inaccessible organ. The subject of pancreatitis is thoroughly considered, both from an experimental and clinical standpoint. The author has done much original work in this line, and particularly in the surgical treatment of chronic pancreatitis by means of drainage of the pancreatic ducts indirectly through the bile tracts. The work can be heartily recommended to all interested in the newer developments in the field of diseases of the pancreas.

OBSTINATE HICCOUGH. The Physiology, Pathology and Treatment, Based on a Collection of Over One Hundred and Fifty Cases from British and Foreign Works. By L. F. B. Knuthsen. Pp. 169. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1902.

The author has devoted 152 pages to more or less complete abstracts of cases found in medical literature. The anatomy, physiology and pathology are treated in three pages, the treatment occupying about two pages of print. The pathology presented is such as might have been expected twenty-five years ago, and has no foundation on pathologic anatomy or on data obtained by modern methods of accurate diagnosis. Fifty-four means of treatment, mostly by the internal administration of drugs, have been used successfully by the authors who have reported cases. The book is interesting as a collection of curious clinical cases, but it does little to advance our knowledge of the causation of hiccough, or of the intelligent treatment of the symptom.

CLINICAL METHODS. A Guide to the Practical Study of Medicine. By Robert Hutchison, M.D., M.R.C.P., Assistant Physician to the London Hospital, etc., and Harry Rainy, M.A., F.R.C.P. Ed., F.R.S.E., University Tutor in Clinical Medicine, Royal Infirmary, Edinburgh. With Upwards of 150 Illustrations and 8 Colored Plates. Fifth Edition. Pp. 612. Chicago: W. T. Keener & Co. 1902.

While the authors of this work do not claim it to be a treatise on medical diagnosis, it contains an immense amount of practical information within reasonable space. It is a book that will be appreciated by the student who is beginning to study clinical cases, and attempting to take histories and make diagnoses. To the practitioner who has not had the advantage of recent laboratory training in the newer methods of exact diagnosis it is also eminently adapted. It can be recommended as reliable and fairly complete.

CLINICAL EXAMINATION OF THE GASTRIC CONTENTS. Illustrated. Paper. Pp. 48. Published by the New York Pharmacal Association, Yonkers, N. Y.

This is an attractive pamphlet and gives the methods employed in the examination of the gastric juices and includes the various tests, such as Ewald's and Boas' test breakfast and double test meal. Also tests for various significations as, for instance, hydrochloric acid, lactic acid, pepsin, etc., etc. There is also a chapter on clinical significance of variations in the gastric contents, and another on the method of using the stomach tube. The pamphlet is illustrated and contains much information of practical value to the practitioner.

ESSENTIALS OF THE DISEASES OF THE EAR, Arranged in the Form of Questions and Answers. Prepared Especially for Students of Medicine and Post-graduate Students. By E. B. Gleason, S.B., M.D., Clinical Professor of Otology, Medico-Chirurgical College, Philadelphia, etc. Third Edition. Thoroughly Revised. Pp. 214. W. B. Saunders & Co.: Philadelphia and London. 1902.

In the preparation of this work, the second edition has been carefully revised and considerable new matter added. Although the subjects discussed are divided by interrogatory headings, the general plan is not questions and answers, but very largely answers to a few leading questions. The plan and scope of the work should enable it to fulfill the object for which it was written.

A TEXT-BOOK OF PRACTICAL MEDICINE. For the Use of Students and Practitioners. By William Gilman Thompson, M.D., Professor of Medicine in Cornell University Medical College. Second Edition, Thoroughly Revised. With 62 Illustrations. Cloth. Pp. 1104. Price, $5.00. Philadelphia and New York: Lea Brothers & Co.

This second edition is a revision of the earlier one, which appeared about three years ago. The additions are not extensive, though the articles on dysentery, yellow fever and malaria have been rewritten, as well as one or two other changes made, and some new matter incorporated, bringing the work up to date.

THE DISEASES OF CHILDREN. By James Frederic Goodhart. Seventh Edition. With the Assistance of George Frederic Still. Pp. 813. Price $5.00 Net. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1902.

In six previous editions, Goodhart's Diseases of Children has been one of the favorite books on this subject both among students and practitioners. The last revision has brought it fully up to date, and the newer matters of interest in etiology and treatment have been introduced.

Marriages.

F. V. CLARK, M.D., to Miss Duval Woodrum, at Roanoke, Va., June 30.

PAUL F. MORF, M.D., to Miss Louise E. Paulus, both of Chicago, July 9.

JOSEPH DAMIANI, M.D., to Miss Josephine Samuelson, both of Chicago, June 30.

ELAN M. RUSSELL, M.D., to Miss Lucy Harris Hart, both of Carthage, Tenn., July 3.

WILLIAM CLARENCE GWYNN, M.D., to Miss Louise Harrison Beall, at Baltimore, June 27.

PAUL S. MERTENS, M.D., Montgomery, Ala., to Miss Francis Sproul White, at Lexington, Va.

WILLIAM ELNATHAN CLARK, M.D., to Miss Frederickke Gorder of Frederick, S. D., July 8.

JAMES THOMAS NUNNALLY, M.D., Griffin, Ga., to Miss Maggie Helen Beaty of Valdosta, Ga., July 7.

J. M. CHITTUM, M.D., to Miss Teresa Smith, both of Richmond, Iowa, at Albert Lea, Minn., June 17.

ARTHUR C. MORGAN, M.D., Philadelphia, to Miss Laura Blake of Bridgeport, Conn., at Philadelphia, June 24.

DANIEL ALLEN PENICK, M.D., Nicholasville, Ky., to Miss Ella Mason Jordan of Ellicott City, Md., June 30.

NOAH ARTHUR BURR, M.D., Springfield, Mass., to Miss Rose Mary Steinway of Great Barrington, Mass., July 1.

Deaths.

Alonzo B. Richardson, M.D.

Dr. Alonzo B. Richardson, Bellevue Hospital Medical College, New York, 1876, medical superintendent of the Government Hospital for the Insane, Washington, D. C.; a member of the American Medical Association; president of the American Medico-Psychological Association; member of the Medicolegal Society of New York, and Ohio State Medical Society; formerly assistant physician and medical superintendent of the Athens (Ohio) Asylum for the Insane, and superintendent of the state hospitals for the insane at Columbus and Massillon, Ohio, died from apoplexy at the Emergency Hospital, Washington, D. C., June 27, after an illness of a few hours, aged 50. The Columbus *Citizen*, in an editorial, thus speaks of "Ohio's Loss and the Nation's":

> In the death at Washington of Dr. A. R. Richardson, Columbus shares its loss with Ohio and the nation. Born and educated in this state, he had done inestimabe service for its unfortunates and only left this field a few years ago at the call of President McKinley to continue his work in the national hospital for the insane at Washington. His death is all the more to be regretted for the fact that he was stricken down in the fullness of his powers when there was promise of still greater achievements for the relief of an army of sufferers.
>
> Dr. Richardson must be numbered among the great Ohioans. In his administration of the hospitals at Athens, Columbus and Massillon he attracted such wide attention that his promotion to the head of the great national institution, to be constructed according to his plans, was but a natural recognition of his services.

The Columbus Academy of Medicine held a special meeting, June 30, to take action on the death of Dr. Richardson, who had once been president of the Academy.

De Laskie Miller, M.D.

Dr. De Laskie Miller, one of the oldest, most prominent and best-beloved physicians of Chicago, died at his home in that city, July 9, aged 85 years.

De Laskie Miller was born in New York City, May 29, 1818. He was graduated from the Syracuse Medical College in 1842, began practice in Lockport, N. Y., then moved to Flint, Mich., and 51 years ago settled in Chicago. Seven years later he was made professor of obstetrics and diseases of women and children in Rush Medical College, and held this chair for twenty years, when he was made professor of obstetrics and diseases of children, and filled this position until 1889.

When Rush Medical College became affiliated with the University of Chicago, Dr. Miller was made president of the board of trustees, and emeritus professor of obstetrics and diseases of children, and in this position he took an active and important part in the work necessary to bring about the affiliation. He was also an advocate of the elevation of medical educational standards and persistently urged betterment in this regard throughout his entire term of service as professor and trustee.

Last winter, on account of increasing infirmities of age, he resigned his position as president of the board of trustees, but the trustees refused to accept his resignation and lightened his duties.

For many years Dr. Miller had an extensive practice, chiefly in the line of obstetrics, but retired several years ago from active work, retaining only a few of his old patients. Dr. Miller was always a student. During his thirty years of

DE LASKIE MILLER, M.D.

active teaching work, his lectures, while scientific in the highest degree, were always entertaining. He was one of the most popular members of the faculty and was greatly beloved by his students. He was always courteous and helpful to the younger men of the profession. He was a member of the American Medical Association, the Illinois State Medical Society, and a life member of the Chicago Medical Society.

His death was the result of heat prostration, which occurred July 3. He was apparently improving from this condition, but on July 4 had a cerebral hemorrhage with slight consequent paralysis from which he also partially recovered. On July 7, however, the hemorrhage recurred, and this was followed by unconsciousness, from which he did not rally, and died on July 9, at 7 o'clock in the morning. He was buried July 12; the interment was private.

Francois Jean Baptiste Rohmer, M.D. Medical College of Louisiana, New Orleans, 1835, died at his home in Mobile, Ala., June 30, aged 90. He was an ardent student of science, and at the outbreak of the Civil War was appointed by Jefferson

Davis surgeon and botanist, and detailed to collect medicinal plants for the use of the forces. He afterward established a laboratory at Mobile for the manufacture of medicines, dressings, etc. He retired from active practice about four years ago.

Julian Harmon, M.D. Cleveland Medical College, 1849, who had practiced at Warren, Ohio, for nearly fifty-four years; assistant surgeon of the Second Ohio Volunteer cavalry in the Civil War; an active member of the Trumbull County, Northeast Ohio, and Ohio State Medical Societies, died at his home in Warren, July 1, from cancer of the mouth, after an illness of three years, aged 79.

Daniel William Lassiter, M.D. University of Pennsylvania, Philadelphia, 1851, president of the Petersburg (Va.) Medical Faculty, died at his home in Petersburg, July 3, after an illness of one year, aged 76. The Petersburg Medical Society, at a special meeting, July 4, adopted resolutions testifying to the great worth and noble character of Dr. Lassiter.

James Dickson, M.D. Homeopathic Hospital College, Cleveland, Ohio, 1875, was shot and killed by his son, who was temporarily insane, at his home in Canal Dover, Ohio, July 2. At the time, Dr. Dickson was suffering from smallpox, and his household under quarantine.

Charles Blodgett, M.D. Berkshire Medical College, Pittsfield, Mass., 1859, for 40 years an esteemed practitioner of Holyoke, Mass., who moved to San Francisco four years ago on account of his health, died suddenly at Grass Valley, Cal., from heart disease, June 25, aged 75.

Abram M. Cary, M.D. Medical College of Ohio, Cincinnati, 1876, for two years a missionary in Laos, Siam, died at his home on Walden's Ridge, Chattanooga, Tenn., June 27, after a lingering illness, aged 57. At one time he served as county physician and as coroner.

Franklin G. Armstrong, M.D. Cleveland (Ohio) Medical College, 1849, a pioneer of Carroll County, Ohio, and in 1866 its representative in the state senate, a resident of the county for seventy-five years, died at his home in Camden, June 24, aged 81.

James H. McNett, M.D. New York University, New York City, 1880, for many years a practitioner of Hornellsville, N. Y., died July 1 at the old homestead near Belmont, from Bright's disease, after an illness of a year and a half, aged 49.

Robert Douglas, M.D. National Homeopathic Medical College, Washington D. C., 1895, died at his home in Washington, D. C., June 25, from consumption, after an illness of three months, aged 58.

V. H. Harter, M.D. Northwestern University Medical School, Chicago, 1902, of Stronghurst, Ill., died at the Cottage Hospital, Galesburg, from appendicitis, June 25, after an illness of one week.

Archer Starel Cook, M.D. California Medical College, San Francisco, 1881, of San Francisco, died suddenly from heart disease, July 1, at the home of his daughter in Oakland, aged 72.

Robert F. Henry, M.D. Rush Medical College, Chicago, 1853, one of the oldest practitioners of Peoria County, died at his home in Princeville, Ill., July 1, from apoplexy, aged 80.

Levi T. Hayward, M.D. Boston University School of Medicine, 1874, or Orange, Mass., died at Cottage City, Mass., June 22, after an illness of five months, from dropsy, aged 54.

Camillus H. Fahnestock, M.D. New York Homeopathic College and Hospital, 1872, died at his home in Laporte, Ind., July 5, from apoplexy, after an illness of two days, aged 56.

David A. Fox, M.D. New York University, New York City, 1852, died at his home in Clinton, Conn., July 1, from disease of the stomach, after an illness of two weeks, aged 74.

George C. Parmiter, M.D. Philadelphia University of Medicine and Surgery, 1868, died at his home in Syracuse, N. Y., June 29, after an illness of thirteen weeks, aged 82.

Amidee F. Voorhees, M.D. New York University, 1852, one of the oldest practitioners of New Jersey, died at his home in Basking Ridge, June 26, from paralysis, aged 79.

Frank Havenstrite McNeel, M.D. Rush Medical College, Chicago, 1881, died recently at his home in Seattle, Wash., from cancer, after an illness of three months, aged 47.

John R. Kimerer, M.D. College of Physicians and Surgeons, Baltimore, 1885, died at his home in Danville, Pa., July 1, from Bright's disease, after a long illness, aged 43.

David Ellis, M.D. University of Louisville, (Ky.), 1852, an aged practitioner of Augusta, Ill., was run over by a passenger train and killed, at Augusta, July 5, aged 80.

Asa V. Hutchins, M.D. Hahnemann Medical College, Chicago, 1883, died at his home in Chicago, July 6, from injuries received in a fall a week previous, aged 59.

Daniel W. Crittenden, M.D. University of Nashville, 1859, died from uremia at his home in Gordonsville, Ky., June 29, after a short illness, aged 70.

Calvin Austin Crowe, M.D. Jefferson Medical College, Philadelphia, 1854, died at his home in Florence, Ala., June 18, after a lingering illness, aged 70.

Richard M. Green, M.D. University of Pennsylvania, Philadelphia, 1856, died at his home in Corsicana, Texas, from asthma, June 18, aged 63.

William S. Dixon, M.D. Pulte Medical College, Cincinnati, 1886, died at his home in Portsmouth, Ohio, June 30, from Bright's disease, aged 64.

Newton J. Rice, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1857, died at his home in Newton Falls, Ohio, June 29, aged 74.

H. C. Van Noy, M.D. University of Michigan, Ann Arbor, 1862, died at his home in Kansas City, Mo., from paresis, July 2, aged 71.

George Howard Kennard, M.D. College of Physicians and Surgeons, Baltimore, died at Silver Lake, Ohio, June 18, aged 43.

James Gerry, M.D. Jefferson Medical College, Philadelphia, 1863, died at his home in Shrewsbury, Pa., July 2, from heart disease.

David H. Bullard, M.D., died at his home in Glens Falls, N. Y., July 1, aged 90. He retired from practice three years ago.

Eugene M. Jones, M.D. Albany (N. Y.) Medical College, 1887, died at his home in Raynertown, N. Y., June 27, aged 43.

L. C. Means, M.D., died at the residence of his son, Dr. Edwin A. Means, Dallas, Texas, July 3, from pneumonia, aged 78.

Charles E. Nash, M.D. University of Missouri, St. Louis, 1849, died at his home in Little Rock, Ark., July 8, aged 79.

John Patterson, M.D. Transylvania University, Lexington, Ky., 1841, died at his home in Auburndale, Fla., June 27.

Robert E. Gatlin, M.D. Tulane University, New Orleans, 1891, died at his home in Summit, Miss., July 1, aged 41.

E. S. Fiske, M.D. New York University, New York City, 1884, died at his home in Towner, N. D., June 28.

W. C. Gordon, M.D., founder of Gordonsville, Texas, was shot and killed in that city, June 28, aged 35.

Francis E. Brocard, M.D., died at his home in New Orleans, June 29, after a long illness, aged 50.

Calvin M. Clayton, M.D., died suddenly at his office in Warsaw, Ind., June 29, from paralysis.

William Rubinstein, M.D., died at his home in Baltimore, July 1, from heart disease, aged 60.

Medical Organization.

Reorganization in New Jersey.

The Medical Society of the State of New Jersey held its one hundred and thirtieth annual meeting, June 23, 24 and 25, at Asbury Park. At its meeting in 1902 a committee was appointed to consider the subject of reorganization, and to report a new constitution and by-laws, if this were deemed advisable. Dr. Philip Marvel, Atlantic City, was made chairman of the committee, and he and his colleagues had given much thought to the subject. A report was presented at the opening session recommending the adoption of the American Medical Association plan, with only such modifications as might be necessary to conform to the ancient charter of the society. The report was taken up at the afternoon session and promptly adopted by a unanimous vote.

This is the oldest state society in the United States. Organized in 1776, and holding regular meetings during all these years, its influence in shaping the medical history of the state has been paramount. As in some of the other original states, it was empowered to examine and license physicians and, after a fashion, to regulate the practice of medicine.

Gradually shorn of these powers by conflicting or adverse decisions, in recent years the society had been mainly instru-

mental in procuring the enactment of an almost model medical examining law, which has the confidence and support of both the profession and people. This law has been construed by the highest courts as regulating the treatment of human ailments by any and all methods, placing New Jersey in line with the most advanced states in this regard.

The personnel of the membership in attendance impressed one as being almost as remarkable as the honorable history of the society itself. It was distinctly a gathering of mature and elderly men. In this and other respects one was constantly reminded of some of the fine old English societies. While the absence of the younger element, which was so noticeable, could not but be a disadvantage to the society, and still more so to the younger members of the profession of the state who deprived themselves of the privilege of attendance, so far as the society itself was concerned, this was compensated for, so far as possible, by the activity and zeal of these mature men. Abreast of the times in scientific work, and fully alive as to all medical and public health affairs, the papers and discussions were fully up to the average at all times. One octogenarian took part in the discussion of a report on a public health question, and spoke with a vigor and clearness beautiful to hear.

Another specially noticeable feature was the intimate relation constantly shown to exist between the society, the State Board of Health and the State Board of Medical Examiners. This was manifested not only in the interest shown in all matters relating to such public affairs, but in the prominence given them in the program and discussions. The retiring president is the secretary of the State Board of Examiners, and the president-elect is the efficient secretary of the State Board of Health. This long-continued union no doubt in part accounts for the ease with which the strong medical and health laws have been secured, and for the public and professional sentiment which made their enforcement possible without the judicial obstacles which have so hampered such work in many other states. It may also account, either as cause or effect, for the fact that over half of the registered physicians of the state are members of the county and state societies, a larger proportion than has been found in any other state except Alabama.

Considered either in the light of its long and honorable history, or of its actual achievements in all the lines of work properly belonging to such a body, any criticism of this society must be in commendation. Its staid, dignified, and somewhat cold proceedings and methods were in striking contrast with the more informal gatherings in other sections, but it was a pleasure and privilege to attend the meeting, and especially to see this conservative body ready to change its fundamental laws as soon as it was found best to do so. It could not but be an advantage to all concerned if the younger men could be induced to attend and take an active interest in the work of the society. This will doubtless be brought about under the new order of things.

Officers.

The following officers were elected for the coming year: President, Dr. Henry Mitchell, Asbury Park; vice-presidents, Drs. Addison W. Taylor, Beverly, Walter B. Johnson, Paterson, and Henry W. Elmer, Bridgeton; corresponding secretary, Dr. Ellis W. Hedges, Plainfield; recording secretary, Dr. William J. Chandler, South Orange, and treasurer, Dr. Archibald Mercer, Newark.

Council.

Drs. Thomas W. Harvey, Orange; John L. Leal, Paterson; Cornelius Shepherd, Trenton; Daniel Strock, Camden, and Philip Marvel, Atlantic City, were elected councilors. The twenty-one counties were divided into five councilor districts, and the proper steps taken to put the new constitution and by-laws into operation without delay, including a card-index for both the state and counties. J. N. McCORMACK.

Boyle County (Ky.) Medical Society.

Physicians of Boyle County met at Danville, June 26, and reorganized the Boyle County Medical Society, with the following officers: President, Dr. F. H. Montgomery, Danville; and secretary and treasurer, Dr. Spurgeon Cheek.

Madison County (Ind.) Medical Society.

This society met in called session at Anderson after due notice from the president and secretary, and unanimously adopted the constitution and by-laws suggested by the special committee of the American Medical Association. This society numbers 60 members, and should greatly increase its membership under the stimulus of the reorganization movement.

New Hanover County (N. C.) Medical Society.

The medical fraternity of New Hanover County met at Wilmington, June 25, and effected temporary organization of a county medical society. Dr. William D. McMillan, Wilmington, was made chairman and Dr. Thomas M. Green, Wilmington, secretary. A committee was appointed to draft a constitution and by-laws in conformity with those of the state society and the American Medical Association.

Northwestern Pennsylvania Medical Society.

On June 4 five county medical societies united at Cambridge Springs to form a district medical society. It is the ultimate aim of the promoters to include several other counties in the district, so as to conform with the district organization of the state medical society. Dr. Clarence W. Coulter, Oil City, was elected president, and Dr. James R. Durham, Warren, secretary. Only members of the county medical societies are eligible to membership.

Jefferson County (N. Y.) Medical Association.

Under the direction of Dr. J. Orley Stranahan, Rome, a meeting was held at Watertown, July 6, to organize a county medical association to be an integral part of the First District Branch, New York State Medical Association. The following officers were elected: President, Dr. Byron C. Cheeseman, Watertown; vice-president, Dr. Parley H. Johnson, Adams; Dr. Florence A. Sherman, Watertown, secretary and treasurer; Dr. Andrew J. Dick, Watertown, delegate to the New York State Medical Association, and Dr. Charles C. Kimball, Watertown, alternate.

Lone Star Medical Association.

This association, whose membership is made up of colored physicians, held its annual meeting at Marlin, Texas, June 16 and 17. The association adopted the constitution and by-laws as promulgated by the American Medical Association. The following officers were elected: Dr. Thomas E. Speed, Jefferson, president; Dr. Henry L. Smith, Waco, vice-president; Dr. R. E. L. Holland, Temple, secretary; Dr. Napoleon T. Atkinson, Greenville, corresponding secretary, and Dr. Rufus S. Childs, Marlin, treasurer. The next meeting will be held in Waco, Texas, in April, 1904.

Lee County (Iowa) Medical Society.

Pursuant to a call issued by Dr. Charles E. Ruth, Keokuk, councilor for the First District of Iowa, the physicians of Lee County met at Fort Madison, July 2, and organized a county society, adopting the constitution and by-laws suggested by the American Medical Association. The election of officers resulted as follows: President, Dr. France C. Roberts, Fort Madison; vice-president, Dr. Frank M. Fuller, Keokuk; secretary, Dr. John Downs, Fort Madison; treasurer, Dr. William E. Sloat, Denmark, and censors, Drs. Emmett C. Chapman, Fort Madison, Tabor R. Washburn, Donnellson, and E. M. Buck, Montrose. The next meeting will be held at Keokuk in October.

Societies.

Harvard University Medical School Alumni Association.—The triennial meeting was held in Boston, June 24. The following officers were elected: President, Dr. Charles F. Folsom, Boston; vice-presidents, Drs. John C. Webster, Chicago; Frederick W. Borden, Ottawa, Ont.; George B. Shattuck, Boston; Erasmus D. Leavitt, Butte, Mont.; Beverly Macmonagle, San Francisco; Isadore N. Bloom, Louisville; Reynold W. Wilcox, New York City; Josiah N. Hall, Denver; Percival J. Eaton, Pittsburg, and Edward F. Cushing, Cleveland; treasurer, Dr. William H.

Prescott, Boston; secretary, Dr. George S. Whiteside, Boston, and assistant secretary, Dr. John G. W. Knowlton, Roxbury, Mass.

New York State Medical Association, Third District Branch.—The nineteenth annual meeting was held in Syracuse and Onondaga Valley, June 25. A new by-law was adopted which states in substance that the council shall hereafter, in compliance with the conditions specified in the article, assume the defense of suits of alleged malpractice brought against members of the society. The council will not undertake the defense of suits brought against a member previous to his membership, and any member wishing to avail himself of the privileges of the article must first sign a contract renouncing his own and vesting in the council sole authority to conduct the defense of said suit in any manner in which may be considered fit. The council will not, however, feel obliged to pay damages in case such are declared by the court. Dr. Frank W. Higgins, Cortland, was elected president; Dr. Franklin J. Kaufmann, Syracuse, vice-president; Dr. Clarke W. Greene, Binghamton, secretary, and Dr. Frank Kenyon, Scipio, treasurer. Binghamton was selected as the next place of meeting.

Ontario Medical Council.—The Ontario Medical Council has been meeting in Toronto during the past week. It has elected for president for the ensuing year Dr. J. A. Robertson of Stratford, Ont., and the Hon. Dr. Sullivan of Kingston as vice-president. Drs. R. A. Pyne and H. W. Aikins of Toronto were re-elected registrar and treasurer respectively. The most important matter which came before the council this year was the report of the special committee on legislation, which suggested amendments to the Ontario Medical Act, which would benefit both the public and the profession. This report stated that it would be wise owing to the amount of quackery prevailing throughout the province for the legislature to clearly define what is meant by the practice of medicine. Following on this advice the medical council provided a resolution bringing these matters to the attention of the legislature. They felt, however, that it would be unwise to do anything more than call the attention of the legislature to irregular unauthorized practitioners at the present time.

MAINE MEDICAL ASSOCIATION.

Fiftieth Annual Meeting, held in Portland, June 3, 4 and 5, 1903.

President, Dr. Hiram Hunt, Greenville, in the Chair.

History of the Association.

DR. CHARLES O. HUNT, Portland, delivered the historical address. Of the 82 practicing physicians who signed the roll at the first meeting in 1853, only 3 are alive to-day, namely, Dr. Alonzo Garcelon, Lewiston, now 90 years of age and still in active practice; Dr. Cyrus Kendrick, Jr., Litchfield Corners, and Dr. Nathaniel T. Palmer, Brunswick. He then sketched the history of the society, the benefits of the medical association to the practitioner, and considered its intellectual value, its fraternal and social benefits and the value of organization. The objects of the association as stated in the constitution are "Mutual professional improvements, cultivation of friendly intercourse between its members, faithful support of regular and honorable practice and the promotion of medical science." He then took up the American Medical Association plan of organization, and suggested that a committee of five be appointed to consider the plan and report at its next annual meeting.

Election of Officers.

At the morning session of the second day the following officers were elected: President, Dr. Augustus S. Thayer, Portland; vice-presidents, Drs. Frederick L. Dixon, Lewiston, and Frank L. Shaw, Machias; corresponding secretary, Dr. Albert H. Sturtevant, Augusta, and treasurer, Dr. Arthur S. Gilson, Portland.

Historical Papers.

DR. JOHN L. M. WILLIS, Eliot, read a paper on "The History of Medicine in Maine Prior to 1853," and DR. WILLIS B. MOULTON, Portland, one "On the History of Medicine in Maine Outside of the Association Since 1853." In 1860 Maine, with a population of 626,297, had 795 physicians and 3 surgeons—one physician to every 1,050 of the population. In 1900, with a population of 694,466, 1,206 physicians were registered—one to every 576 of the population. The increase in the population in the forty years was about 10 per cent., while the percentage of increase of physicians was more than 51.

Banquet.

The annual banquet was held June 4. Dr. Edwin Fuller, Bath, presided as toastmaster. He called attention to the presence of two of the charter members of the association, the venerable Dr. Alonzo Garcelon and Dr. Cyrus Kendick. Among the toasts responded to were those on "The Relation of Theology to Medicine," "The Relation of Literature to Medicine," "The Relation of the Alienist to the Medical Profession," "The Relation of Good Fellowship to Medicine," and "The Relation of Medicine to the Student."

Entertainment.

After the adjournment of the business session about 150 members enjoyed a sail down Casco Bay and a shore dinner at Long Island.

SOUTH DAKOTA STATE MEDICAL ASSOCIATION.

Twenty-second Annual Meeting, held at Mitchell, May 27 and 28, 1903.

The President, Dr. J. O. Duguid of Springfield, in the Chair.

The Committee on Reorganization.

DR. R. C. WARNE of Mitchell, chairman, reported in favor of adopting the recommendations of the committee on reorganization of the American Medical Association. The report of the committee was adopted without change.

By this action the state is divided into nine councilor districts (with one society in each district). A number of excellent papers were read. Dr. H. E. McNutt gave an interesting account of the passage of our model medical practice law. A vote of thanks was tendered Drs. McNutt and J. R. Hawkins for their good services in securing medical legislation.

Election of Officers.

The following officers were elected: President, Dr. B. A. Bobb, Mitchell; vice-presidents, Dr. C. B. Mallery, Aberdeen, and Dr. J. G. Parsons, Brookings; secretary-treasurer, Dr. William Edwards, Bowdle; assistant secretary, Dr. F. M. Crain, Redfield. Councilors: Dr. Daniel Geib, Groton; Dr. E. T. Ramsey, Clark; Dr. J. E. Coulter, DeSmet; Dr. O. R. Wright, Huron; Dr. A. J. Doty, Colman; Dr. F. L. Freyberg, Mitchell; Dr. J. R. Hawkins, Sioux Falls; Dr. C. C. Gross, Yankton; Dr. W. G. Smith, Sturgis. Members of the house of delegates: Dr. H. J. Rock, Aberdeen; alternate, Dr. C. J. Lavery, Fort Pierre. Place of next annual meeting, Redfield.

The association was handsomely entertained by the citizens of Mitchell and banqueted by the Mitchell District Medical Society.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

Minutes of the Thirteenth Annual Meeting, held at New Orleans, May 4, 1903.

List of Representatives.

The Association convened in the Auditorium of Artillery Hall, and was called to order at 2:30 p. m. by the president, Dr. Wm. L. Rodman, Philadelphia.

The following colleges (45) were represented by delegates:

Arkansas Industrial University Medical Department: Edwin Bentley.

Denver and Gross College of Medicine, Denver, Colo.: Thos. H. Hawkins.

Columbian University Medical Department, Washington, D. C.: Thos. A. Claytor.

Georgetown University Medical Department, Washington, D. C.; Geo. M. Kober.

American Medical Missionary College, Chicago, Ill.: E. L. Eggleston.

College of Physicians and Surgeons, Chicago, Ill.: W. A. Evans.

Illinois Medical College, Chicago, Ill.: H. H. Brown.

Northwestern University Medical School, Chicago, Ill.: W. S. Hall.

Rush Medical College, Chicago, Ill.: J. M. Dodson.

Ft. Wayne College of Medicine, Ft. Wayne, Ind.: M. F. Porter.
Medical College of Indiana, Indianapolis, Ind.: D. A. Thompson.
Iowa College of Physicians and Surgeons, Des Moines, Iowa: Lewis Schooler.
College of Medicine, State University of Iowa, Iowa City, Iowa: J. H. Guthrie.
Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa: G. R. Jenkins.
Kansas Medical College, Topeka, Kans.: W. S. Lindsay.
Hospital College of Medicine, Louisville, Ky.: P. R. Taylor.
Kentucky School of Medicine, Louisville, Ky.: W. H. Wathen.
University of Louisville Medical Department, Louisville, Ky.: J. M. Bodine.
Kentucky University Medical Department: T. C. Evans.
Flint Medical College, New Orleans University, New Orleans, La.: H. J. Clements.
Baltimore Medical College, Baltimore, Md.: D. Streett.
Baltimore University School of Medicine, Baltimore, Md.: W. O. B. Sellman.
College of Physicians and Surgeons, Baltimore, Md.: C. F. Brown.
University of Maryland School of Medicine, Baltimore, Md.; R. Winslow.
Woman's Medical College, Baltimore, Md.: H. Harlan.
College of Physicians and Surgeons, Boston, Mass.: C. M. Cobb.
Detroit College of Medicine, Detroit, Mich.: H. O. Walker.
University of Minnesota College of Medicine, Minneapolis, Minn.: J. H. Fulton.
Kansas City Medical College, Kansas City, Mo.: T. J. Beattie.
University Medical College of Kansas City, Kansas City, Mo.: S. C. James.
Marion Sims-Beaumont Medical College, St. Louis, Mo.: H. W. Loeb.
St. Louis College of Physicians and Surgeons, St. Louis, Mo.: C. W. Lillie.
Jno. A. Creighton Medical School, Omaha, Neb.: H. L. Burrell.
University of Nebraska College of Medicine, Lincoln, Neb.: H. B. Ward.
University of North Carolina Medical Department, Chapel Hills, N. C.: R. H. Whitehead.
Miami Medical College, Cincinnati, Ohio: J. Eichang.
Cleveland College of Physicians and Surgeons, Ohio: A. R. Baker.
Ohio Medical University, Columbus, Ohio: W. J. Means.
Jefferson Medical College, Philadelphia, Pa.: J. W. Holland.
Medico-Chirurgical College of Philadelphia, Pa.: Seneca Egbert.
Woman's Medical College of Pennsylvania, Philadelphia, Pa.: W. L. Rodman.
Meharry Medical College, Nashville, Tenn.: G. W. Hubbard.
University College of Medicine, Richmond, Va.: Stuart McGuire.
Milwaukee Medical College, Milwaukee, Wis.: W. H. Earles.
Wisconsin College of Physicians and Surgeons, Milwaukee, Wis.: A. H. Levings.

The minutes of the Saratoga meeting, as printed in the proceedings, were accepted with the following corrections: (1) The minutes to show that the Kentucky School of Medicine was represented at the Saratoga meeting. (2) That the name of Dr. J. W. Chambers be inserted in place of that of Dr. Robert Reyburn at the bottom of page 6.

President's Address.

The first vice-president, Dr. R. H. Whitehead, then took the chair, while the president, Dr. Wm. L. Rodman, delivered the presidential address.

In the first place, it is my pleasure to cordially thank you for the distinguished compliment shown in choosing me as your presiding officer for this meeting. Believing that this would prove to be a critical year in the life of the Association, I assumed office with many misgivings as to my own ability to safely advise and direct the Association's affairs.

It has seemed to me best to follow the beaten paths trodden by my illustrious predecessors and spend the brief time allotted in making a few general recommendations concerning the present needs of the Association. I can not hope to say much that is new, but will endeavor to emphasize that which seems to me true. In doing so, I trust that I will give offense to none, and that I will be credited with an honest endeavor to advance the interests of this Association and to further the cause of medical education, which has ever been its prime object.

In appointing a committee at the last meeting to amend Article III of the Constitution, a judicious step was taken by the Association and one which I am sure will result only in good. The personnel of the committee should command for their carefully prepared reports the respectful consideration of all the assembled delegates. It is to be regretted, I think, that more sweeping authority was not given this excellent committee, so that other amendments, as needful perhaps as those submitted, could have been suggested. The whole constitution and by-laws should be rewritten and made to conform to the requirements of the present time. In many respects they are absolutely wanting, in others vague, and in others still the opposite of what they should be. I would, therefore, suggest the continuance of this committee in the work so well begun, with instructions to present any changes in the constitution and by-laws which may seem necessary at the next annual meeting.

I am pleased to announce that the deficit existing at the last meeting has been entirely liquidated and that there is a sufficient balance in the treasury to meet the Association's obligations during the current year. It could not have been possible, however, without raising the membership fee to ten dollars. This very necessary change will save the secretary many annoyances of a financial nature in the future, and insure, among other things, the prompt publication of the minutes of our meeting. Moreover, a fund will soon be created which can be still further increased, if necessary, by direct assessment to provide for the inspection of all the schools members of the Association. Such a step now seems to me necessary, and I would recommend that the secretary be requested to make, or cause to be made, an examination of the plants and equipments of all the colleges forming the Association, and to report thereon as soon as practicable. By taking one-third of the schools each year, a perfectly satisfactory examination could be made as to their didactic, clinical and laboratory facilities, and the result of such examination be reported on fully at the next annual meeting. Such an examination and report would do more, in my judgment, than any other step that could be taken. Poorly equipped institutions would be slow to seek admission into the Association if they were required to pay the expenses incident to a proper examination of their plant and to abide by the result of such a report made to the Judicial Council. It is easy to comply on paper with all necessary requirements. Some attempt at least should be made to hold schools responsible for what they advertise. This, seemingly, is the only way of doing so.

Membership in this Association has been like salvation, entirely too free in the past, and it can not be denied that the stronger and better schools holding membership are more than restive under the careless admission of some and the continuance in good standing of others that have sinned grievously and palpably. What we need is not more members, but better ones, so that schools seeking admission will do so because it will be both a credit and an honor to belong to the Association of American Medical Colleges, and not as is true now of some, simply for the reason that it is to their commercial advantage to do so. I am neither optimistic nor Utopian enough to believe that all the members of this Association can be of equal merit, any more than can all men or all practitioners of medicine. This is unnecessary. It is the privilege of the strong to support the weak so long as they deserve it, but it is not the duty of those who are virtuous and support the law to shield those who voluntarily transgress it. The Association fixes a minimum standard and pretends to require that all of its members live up to their obligations. They are not doing it, and everyone in this audience who is advised knows it.

JUDICIAL COUNCIL.

That many schools have sinned in the past is to be inferred from the promptness with which unanimous verdicts of the Judicial Council have been set aside by the Association when charges have been both sustained and admitted. We should either support the Council when we believe it to be right or do away with the farce of mock trials altogether. We should not allow the good fellowship of teachers to excuse glaring faults in the schools they represent, a sin easily committed. The work of the Judicial Council is tedious, and somewhat disagreeable, and those who are willing and capable of serving the Association in this capacity should be supported in all reasonable recommendations. They will always give the ac-

cused the benefit of doubts, and the Association can add something to their leniency if it seems best; but to deliberately set at naught the verdicts of a unanimous jury would hardly be countenanced by the most lenient of judges.

FEES.

This body has in the past declined to recognize or discuss the question of fees. So far as fixing a minimum rate, as is done by the Association of Dental Colleges, there are, I admit, two sides to the question. Personally, I favor it and think the time has come to say that no school holding a cheap estimate of its own work shall become a member of this Association. But as to another question, namely the reduction of fees under one pretense and another, there is but one side. This, to my mind, from verbal and written evidence, is the greatest evil from which the Association is now suffering. It can only be stopped by saying that all members shall live up to their published announcements and collect the amounts specified in their catalogues. While I am strongly in favor of a minimum charge of one hundred dollars, and consider this sum really less than a first-class course in medicine can be had for at the present day, still I would be willing to say, let a school charge whatsoever it may please, but require that it collect that amount, and collected in money and not in services or any other questionable way. So flagrant have been the transgressions along this line that it is believed by many that a sufficient forfeit evidencing the good faith of the institution should be required of every member of the Association. I see much in the suggestion to warrant its trial, and believe that it would certainly have a repressive influence if it did not absolutely prevent this blighting evil.

SCHOLARSHIPS.

Some schools have shown scant regard for resolutions hitherto passed by the Association in reference to scholarships. This is an evil parallel to the cutting of fees and should, so far as possible, be eliminated.

TRANSFER OF STUDENTS.

While the constitution is clear enough as to the privileges of members to deal with the students of other schools at the beginning of a session, it has nothing to say on the important question of transferring students in the midst of a term. Undoubtedly this is a subject demanding attention. It is a practice to be discouraged in the main, for nearly always the student wishes to change schools during a term for reasons altogether selfish and discreditable to himself. Occasionally the right will be on his side, and if his record has been good, if all reasonable requirements have been met and the Dean will so certify, there is no just ground for refusing him admission to the same class in another school. It should be made impossible, however, for any work of importance, didactic, clinical or laboratory, to be evaded.

THE ADVANCED STANDARD OF ADMISSION.

There is a pretty general feeling, and it is frequently expressed, that this Association must advance its standard at the present session or it is in great danger of going to pieces. A spirit of magnanimity has been shown for some years by schools whose standards are in many respects ahead of the Association's requirements in the hope that an advance could be made with the hearty co-operation of nearly if not all members. This hope, I trust, has not been illusory. There has been little or no advance made in the Association's requirements since 1895, a long time in this somewhat remarkable era of progress. The result of it is that the Association, which was at one time the leader in medical education, now finds itself led by nearly all of the progressive commonwealths of the country. We are in a position that simply can not and should not continue. I have the greatest sympathy and respect for a small school with no endowment and moderate equipment endeavoring to and succeeding in doing excellent work, though sandwiched in between strong schools on one side and inferior (low grade) ones on the other, such a small school naturally may be slow to favor an advance, fearing that it will suffer thereby. But the fact of the matter is that in the past none of us has ever suffered as much by advancing the standard, as we feared, and do what we will there seems every year an increasing number of students that must go somewhere. There is, moreover, a better appreciation of the small, select school at the present time than ever before, on account of the superior clinical facilities offered toward classes and to sections in the laboratories. Large classes can not be handled so well now as formerly, and this fact is keenly appreciated by medical students. Therefore, it would seem that the best way for any school of precarious existence to increase its matriculation list is by advancing its standard and increasing its facilities. Every year it seems to me that students get to be more discriminating, and certainly every year there is a greater tendency for the better ones to shift from one school to another. One year ago I insisted that our faculty raise its fee to $150, and at the same time made it impossible for any reduction to be given on any account whatsoever. It was feared that it would seriously curtail our freshman class of 1902, yet it was much the largest we have ever had. (To those who can not see things in this light and believe that their schools can only continue under the present standards, I can only say that the way for honorable withdrawal is open to them, and while we should regret to see a single member of the Association leave it, we should prefer that many would go rather than see the Association refuse to do what all of the better schools want and ask for, and an overcrowded profession demands.) No one will deny that there are too many schools and too many practitioners in this country; there are more schools in one city than in the entire Empire of Russia.

How shall the standard be raised? First, the entrance requirements must be raised. Second, no advanced standing should be given to any one having a degree, unless it is demonstrably equivalent to the freshman year in medicine. Third, the session should be lengthened. Fourth, mid-year examinations should be encouraged. No one will question that the requirements for matriculation are far below what they should be. The time has come when this Association can not maintain the respect of the profession and the several state boards of examiners unless it requires a high school diploma, or its equivalent, of matriculants in a medical college. I am not prepared to go so far as the committee and demand that the diploma be from a four years' high school; for, desirable as that is, I fear that it would be requiring more than is feasible or right. In the State of Pennsylvania, for instance, there are 193 high schools, more than two-thirds of all the high schools in the entire state, with less than a four-year course. If such is the case in Pennsylvania, which is certainly one of the oldest, wealthiest, and most favored commonwealths, the conditions are not likely to be better in many states of the Union, but in most of them actually worse. It is not equity, I admit, to put on the same footing men with two, three and four-year high-school diplomas, and it is discriminating against the city boy who will necessarily go to the best high schools with the longest courses. If there must be a favored class it should be the country boys or those from small towns, for, as a rule, they begin school later, have less means, and finally will in all probability settle in the country, where less is required and expected of them. The boy raised in the city is pretty certain to remain there, where competition is sharpest, and he should, therefore, be prepared for it in every possible way.

To say that we will require a high school diploma without qualifications will, I think, be an enormous gain, and as long a step forward as the Association is willing to take. Personally, I favor the four-year diploma, but if we can get to that point in three or five years as an Association representing so many of the states, we will be doing very well. It is only fair to give reasonable notice that such rigid requirements will be enforced so that boys contemplating the study of medicine can prepare for it by taking a four-year high-school course. Therefore, I should say, advance at once to a high school diploma, and in either three, or at most five years, require a four-year diploma or its equivalent. An examination as outlined by the committee in lieu of a diploma should always be permitted. It is unfair and undemocratic to say that every matriculate must be the possessor of a diploma. If he has the knowledge entitling him to one, that is sufficient, and there may be the best of reasons why a student in every way worthy failed to get his degree. A bill, excellent in many respects and deserving of support, lay and professional, failed of passage by the recent legislature of Pennsylvania because it did not provide for an examination of those who were self taught, or at least without diplomas. It passed the lower house by a large majority and undoubtedly would and should have passed the senate but for this unfortunate and fatal omission.

ADVANCED STANDING.

The report of the committee appointed recommends "that credit for one year be given to students holding the degree of A. B., B.S., or other equivalent from a reputable university or literary college." The minority report would withhold advanced standing to those with baccalaureate degrees. I should prefer to take a middle course and grant advanced standing only to those who have specially fitted themselves for the study of medicine. No other course, in my judgment, so well

prepares one for a professional career as a two or three years' course in the biological sciences. I have never favored the idea of granting advanced standing for any cause whatsoever, and have believed it best to require four years in a medical school. I am quite sure, and in this belief nearly all concur, that it was a mistake to give a one-year credit to dentists, pharmacists and veterinarians; a majority of the schools have discontinued the practice. I have never known of many instances where such students were not greatly handicapped throughout their entire medical career. It would seem that there is less reason for giving one year's credit to a student with an A.B. degree. Under this ruling many schools are still granting advanced standing to even high school graduates, and are really giving only a three years' medical course. It was never, I think, contemplated by the Association that the present law would be so construed, but that it has been made very elastic, and an excuse for a short cut to a diploma in many instances, there can be no doubt. It may be safer, as the author of the minority report says, to give no advanced standing to any one, but in lieu thereof to allow credit for work actually done. This is the ideal method, I admit. Practically, however, we find the biological courses in most of the eastern colleges quite the equal in every way of the freshman year in medicine, and students with such degrees easily take their places in the sophomore class and acquit themselves creditably. I have never known one to fail in the final examination before his faculty, or before a state board. Such has also been the experience of Jefferson College. Such students come with a disciplined college training and, moreover, have what all others claiming advanced standing have not, a good knowledge of anatomy, both comparative and human. I know that the presidents of all the colleges in Pennsylvania have shown great interest in their biological courses and have designed them especially for those intending to study medicine. More than two years ago, when they were all invited to take part in a discussion before the Philadelphia County Medical Society, the subject of advanced standing being then a live one with the medical schools of Philadelphia and the Pennsylvania State Board, a good account was given by the colleges represented, and most of us were surprised at the completeness of their biological courses. Since then the schools of Philadelphia have not hesitated to admit such students to advanced standing, though denying it to all others.

LENGTH OF TERM.

I heartily endorse the recommendation of the committee that this Association require as a minimum a seven months' term. Some of the best schools require nine, more eight and all should require at least seven months. The very proper action of the several state boards of examiners in demanding longer terms has made this advance absolutely unavoidable. I should prefer to see the term eight months instead of seven, as some of the state laws require it now, and others will do so very soon. This Association should lead and not be driven.

MID-YEAR EXAMINATIONS.

The time has come when this Association should encourage, if not require, mid-year examinations in writing, as is done by nearly all of the best literary colleges. Our frequent quizzes are all very well in their way, but do not prepare students for their examinations before state boards, which are invariably in writing. Men only learn to write good papers by practice, and if they were required to undergo written examinations twice a year instead of once, it is reasonable to suppose that by the end of their senior year they would present very much better papers and appear to greater advantage before the several state boards.

Every year I find the papers of the senior students much better in construction, spelling, etc., etc., than those of the juniors, which I can only explain in two ways: First, by their larger experience in written examinations; second, by the result being of greater moment to them. If the junior fails to secure a passing mark, he is conditioned; if the senior does not come up to the standard, he fails of graduation. This naturally indicates that the final examination of freshmen, sophomores and juniors should be, what they are not, as a rule, I fancy, even more rigid than the examinations of seniors. It is fairer and more just in every way to hold up a man and let him know where he stands before reaching the senior class. It is certainly most unjust to throw out a student at the end of his senior year for either bad writing, spelling, English, or all. This should be done when he applies for matriculation, and in the event of his shortcomings not being detected then, they certainly should be at the end of his freshman year. I do not teach the freshman or sophomores but the juniors and seniors, and each year I condition in surgery three times as many juniors as I vote against seniors. It is rarely the case that a conditioned man comes up lame the following year. Moreover, they are almost invariably grateful for the warning given, and meet their fate with a philosophy that a senior can not be expected to show. From an experience in four faculties during the past fifteen years I am led irresistibly to the conclusion that the senior examinations are *about* what they should be, but the examination of underclassmen is frequently little more than a sham.

In conclusion, I should say that the most pressing and needful reforms at present necessary are an increase in the preliminary requirements before matriculation, with better teaching and more rigid examination of underclassmen.

On motion of Dr. W. J. Means, the address was referred to a committee of three to report at the evening session. The chair appointed on this committee Drs. H. O. Walker, J. W. Holland and H. B. Ward.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Gonorrheal Arthritis.

E. C. Hill, in *Med. Standard*, gives the following methods of dealing with arthritic joints due to gonorrhea, which have been prescribed by different authors:

Potassium iodid, grains 5 in a tablespoonful of water every hour or two.

Syrup of iodid of iron, dram one half, gradually increased.

Treat the focus of infection in the urethra.

Apply to the joint an ointment as follows:

℞.	Ol. terebinthinæ		
	Acidi salicylici		
	Lanolini, āā	℥iii	12
	Adipis	℥iii	90

M. Ft. ung. Sig.: Apply locally.

An injection of mercuric chlorid solution is sometimes recommended as follows:

℞.	Hydrarg. chloridi corros.	gr. i	06
	Sodii chloridi	gr. x	65
	Aquæ destil.	℥i	30

M. Sig.: Inject three to five hypodermic syringefuls into the joint at intervals of three days; or:

℞.	Guaiacol	3ii	8
	Olei olivæ	3vi	24

M. Sig.: Apply to the skin over the affected joint four times daily.

Aspiration of the sero-purulent effusion, followed by compression of the joint and fixation of the limb in immovable dressing. Massage and hot and cold douches to aid absorption.

Ozena.

Voquier, in *Jour. des Pract.*, recommends, in the treatment of ozena, that the surfaces be thoroughly cleansed and the dried crusts removed by warm douches containing sodium chlorid, sodium bicarbonate, or lysol in solution, after which one of the following ointments should be applied by means of a swab or small brush:

℞.	Menthol	gr. ivss	30
	Acidi borici	gr. xxx	2
	Liq. petrolati	℥i	30

M. Sig.: Apply locally three times a day; or:

℞.	Naphthol	℥i	4
	Resorcin	gr. xv	1
	Liq. petrolati	℥i	30

M. Ft. unguentum. Sig.: Apply locally; or:

℞.	Diiodoformi	℥i	4
	Liq. petrolati	℥v	20

M. Sig.: Apply locally.

Some preparation containing iodin has always served a good purpose in these foul-smelling conditions. The iodin may

be applied as follows, after applying a weak solution of cocain to anesthetize the parts:

℞.	Iodi	gr. v	30
	Pot. iodidi	gr. xv	1
	Aq. destil.	ʒiss	6

M. Sig.: To be applied locally by means of a cotton swab or applicator.

Aperient for Pregnant Women.

Lutaud, in *Nouveaux Remèdes*, recommends the following combination to relieve the constipation of pregnant women:

℞.	Olei ricini	ʒi	30
	Syr. rhei	ʒv	20
	Spts. frumenti	ʒss	15
	Essentiæ menth. pip.	m. ii	12

M. Sig.: To be taken at one dose.

Urticaria.

The *Medical World* recommends, in the treatment of urticaria, that the patient be placed on some combination containing calcium chlorid as follows:

℞.	Calcii chloridi	ʒii	8
	Tinct. aurantii flor.	ʒvi	25
	Aq. chloroformi q. s. ad	ʒvi	180

M. Sig.: One to two tablespoonfuls to be taken three times a day.

In addition the patient should be instructed to take a bath containing soda or borax. The elimination from the bowels and kidneys should be carefully watched.

Pertussis.

Rothrock, according to an abstract in *Med. Standard*, advises, in the treatment of pertussis, that expectorants be administered in the catarrhal stage. He recommends the stimulating expectorants such as ammonia, scilla, senega, etc. Either the carbonate or chlorid of ammonium may be given.

In the second stage sedatives are indicated, such as belladonna, cannabis, indica, codein, passiflora and conium. The following combinations are recommended by the author:

℞.	Tinct. belladonna	m. xxiv	1 65
	Sodii brom.	ʒiii	12
	Syr. tolutani	ʒiii	90

M. Sig.: Five to twenty drops at a dose.

The following containing grindelia robusta is also recommended:

℞.	Tinct. grindelia robustæ	ʒss	15
	Spts. vini rectif.	ʒss	15
	Acetanilidi	gr. xxiv	1 65
	Syr. acaciæ	ʒiii	90

M. Dissolve the acetanilid in alcohol and add to the other ingredients. Sig.: Ten drops to a child of one year; to a child of 8 or 10, the dose may be increased to 20 or 25 drops every two hours.

℞.	Cochineal	gr. x	65
	Sodii bicarb.	gr. xii	75
	Pot. brom.	gr. xv	1
	Tinct. belladon.	m. xv	1
	Tinct. card. co.	ʒi	4
	Aquæ cinnamomi	ʒii	60

M. Sig.: Twenty to thirty drops every four hours; or:

℞.	Acidi hydrocyanici dil.	m. viii	50
	Tinct. ipecacuanhæ	ʒi	4
	Syr. tolutani	ʒi	30
	Aquæ	ʒi	30

M. Sig.: Ten to twenty drops every three or four hours.

The author also recommends drosera as of value in relieving the paroxysm, given as follows:

℞.	Ext. droseræ fl.		
	Ext. ipecac fl.		
	Tinct. nucis vomicæ, āā	m. v	30
	Aquæ q. s. ad	ʒiv	120

M. Sig.: One teaspoonful at a dose.

Bromoform is also recommended in 2 to 4 drop doses. Ichthyol, one teaspoonful added to 4 or 5 ounces of water and used as an inhalation, is of service.

The author condemns the use of opium, substituting codein in doses of gr. 1/100 to gr. 1/32, according to the age of the patient.

If the patient vomits to any extent, cerium oxalate should be given, as it acts on the pneumogastric nerve.

He has obtained good results from passiflora incarnata as an antispasmodic, sedative, tonic and eliminant. It is a safe remedy given in teaspoonful doses of the tincture every two or three hours.

G. Macridés, in *Jour. de Med. Interne*, recommends the following formula in the treatment of whooping cough:

℞.	Bromoformi	gtt. 1	3 30
	Syr. belladonnæ	ʒvi	25
	Aq. destil.	ʒiii	90

M. Sig.: One teaspoonful three or four times a day for a child over six years of age.

Medicolegal.

Sodomy.—The Court of Criminal Appeals of Texas holds, in Almendaris vs. State, that under a charge of sodomy, carnal knowledge, such as is essential to the crime of rape, must be proved, though the jury may infer penetration from the circumstances, without direct proof. And the Court of Appeals of Kentucky holds, in White vs. Commonwealth, that, while the decisions have not been uniform, the drift of the later decisions in both the English and American courts is to hold that nothing more than *res in re*, without regard to the extent of the penetration or emission, is all that is required.

Insufficient Evidence of Practicing Without License.—The Supreme Court of Washington says that the acts constituting the practice of medicine charged in the case of State vs. E. Dunham were that at a certain time and place the latter "did wrongfully and unlawfully establish and maintain an office, and advertise the title of doctor" in a certain newspaper. No attempt at all was made to prove that he maintained an office, and the only evidence introduced as to the other fact was a paper containing an advertisement. Clearly, the court holds, there was here no proof of the crime charged, namely, the practicing of medicine without a license. As against the presumption of innocence, it could not be presumed from the mere fact that an advertisement appeared in a paper that it was authorized by the accused, nor would it be presumed that he was the person named in the advertisement, though the name therein and his name were the same.

Liability for Disease Resulting from Injuries.—In the personal injury case of Wood vs. the New York Central & Hudson River Railroad Company, where the decline of the party suing had been substantially uninterrupted, until consumption had supervened, ascribable to the shock and muscular strain of an accident, the Fourth Appellate Division of the Supreme Court of New York says it assumes that if there is a progressive, complete connection between any diseases and the injuries inflicted, such disease may be taken in estimation by the jury, as the party suing is entitled to recover for any damages which are the proximate result of the injuries. It is a matter to be determined by the jury, and the causal connection between the injuries and the existing disease must depend in a considerable degree on the evidence of physicians. The right to embrace in the recovery damages for an existing disease may not be lost by reason of the length of time which has elapsed between its discovery or inception and the infliction of the original injuries, nor on the character of the disease. The fact may be established that the disease was the result of the injuries; that the association of the two is by a direct line; and their connection is not to be based on conjecture or speculation. If their unbroken connection is thus demonstrated, then the cause of action of the party suing may include the disease.

Without Contract Town Not Liable for Medical Services.—The Supreme Court of Mississippi holds, on the appeal of the Town of Pass Christian vs. Washington, an action brought by the latter party, a physician, to recover for services rendered in treating four cases of smallpox and preventing the spread of the disease, that the whole case failed for the want of any valid

contract for these particular services with the city. After the physician's discovery and reporting of these cases, the mayor directed him to do what was necessary, and the board of mayor and aldermen made an order that he be appointed health officer of the town, and be requested to take at once the necessary sanitary precautions for the general good of the health of the town. The Supreme Court says that this order was a mere appointment of the physician as a health officer, vesting him with the usual authority with respect to sanitary precautions for the good of the town. It was in no sense a contract to treat these four smallpox patients, and no other valid contract for that purpose was shown. Without a contract, it declares, there is no liability on the part of the town. And to much the same effect is the decision of the Supreme Court of New Hampshire in the scarlet fever case of Pettengill vs. the Town of Amherst. It says that the verdict of the jury established the fact that the services of the physician suing were not rendered at the request of the town, or under any contract with it therefor. The board of health did not employ, or attempt, as statutory agent of the town, to pledge its credit for his services rendered in this case. The board did not deem it "wise or necessary" to employ him in this case at the expense of the town, to use the words of the statute which provides that in cases of quarantine the board may render assistance when deemed wise or necessary. Whether there was a moral obligation, under the circumstances, resting on the board and the town to provide the party in question with medical attendance during the confinement of his family in quarantine, was immaterial in this action. The town could only be liable on a legal contract, which the case showed did not exist.

Libel on Physician in Board of Health Preamble.—The Ohio case of Mauk vs. Brundage and others was brought by a physician against the members of the board of health of a village for libel in causing to be published in a newspaper: "An order to prevent and restrict infectious diseases. Whereas, the board of health of the village of Delphos, Allen and Van Wert counties, Ohio, after careful consideration, has become satisfied that in said village a number of deaths have recently resulted from the carelessnesss and negligence of the physician attending the patients in childbirth soon after attending and handling other patients affected by blood poison and other infectious diseases, and that from the same cause others in said village have greatly suffered and barely escaped death: Therefore, it is hereby ordered by the board of health of the village of Delphos, Allen and Van Wert counties, Ohio, that no physician and surgeon or midwife or other person who has heretofore or may hereafter practice or attempt to practice medicine, surgery, or midwifery in any of its branches, shall within said village attend as physician, surgeon or midwife, or touch or handle, any woman in childbirth, nor perform any act of surgery, or touch the mucous membrane of any person within thirty days after such physician and surgeon, midwife, or other person practicing or attempting to practice medicine, surgery, or midwifery has touched or handled any person affected with blood poison, gangrene, erysipelas, or other infectious disease, except in continuing to treat his or her patients affected with the same, and no other infectious disease." The answer of the members of the board admitted the passage by them of the preamble and order as charged, and that the same was placed on the record of the board's proceedings, but averred that they passed the order as members of the board of health; that they had reasonable and probable cause to believe and did believe the facts stated to be true, and published the same under an honest belief that such publication was required of them in the due discharge of their official duties as such board, and denied that the same was published maliciously, or with any intent to injure the party suing. The Supreme Court of Ohio holds that the preamble, construed in connection with the order and the pleadings, was libelous per se, or by itself, and the publication of it was not privileged. It was the duty of the court to so instruct the jury, and not to submit those questions for their determination. On showing by a preponderance of the evidence that the preamble was published as charged, and that the party suing was the physician intended by the members of the board and understood by the community as such physician, he was entitled to recover at least such compensatory damages as were attributable to the publication. If, in such case, the evidence warranted a finding that in the passing and publication of such preamble some of the members of the board were actuated by express malice and others were not, and the jury should so find, it would be proper practice to render a verdict against all of the members for compensatory damages, and an additional amount as exemplary damages against those found to have been guilty of express malice. The result to be reached in the present instance, the court says, was the order providing for the conduct of physicians in the village. To reach this result, however imminent the duty of the board to pass and publish a proper resolution to correct the evil which it was assumed existed, it could not be at all important to charge negligence on the part of any physician. Not being essential, or even important, that the board should undertake to fix the blame on any particular person, it followed that the preamble was not a privileged communication, and that those who passed and published it assumed the responsibility as individuals, and could not shield themselves by merely showing that they acted as members of the board, and that the order itself was a proper one.

Current Medical Literature.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.

July 4.

1 *Arterial Sclerosis as a Cause of Nervous Disease. M. Allen Starr.
2 *The Anatomy of Portal Anastomosis. Rolfe Floyd.
3 *Synopsis of Experiments on the Transformation of Circulating Uric Acid in the Organism of Man and Animals. Alfred C. Croftan.
4 How May We Cure Posterior Displacement of the Uterus? Augustin H. Goelet.
5 *Tent Life for Consumptives. J. Edward Stubbert.

1. Arterial Sclerosis in Nervous Diseases.—The importance of endarteritis in the etiology of nervous diseases is insisted on by Starr. In 200 consecutive cases of apoplexy of which he has records in private practice, in 80 per cent. there were distinct prodromal symptoms which had been regarded at the time as neurasthenic, but which are more readily explainable under the law of malnutrition due to arterial disease. He thinks if the condition of the blood vessels and the heart muscles were thoroughly investigated for the possible existence of accentuated second sound, and the tension of the arteries not only in the wrist, but elsewhere, and the condition of the kidneys were studied, the so-called neurasthenia would be more apt to yield to treatment than by the use of remedies directed particularly to the nervous system. He also remarks that it is not so commonly known that the majority of diseases of the spinal cord are equally traceable to the vessel wall where direct infection is not shown. Vascular disease is found in poliomyelitis, bulbar palsy, myelitis, spastic paralysis, so-called senile paraplegia and combined sclerosis, all of which can be traced often to arterial degeneration. Diseases of the peripheral nerves are also occasionally due to endarteritis, as in case of alcoholic neuritis. The facts in regard to the occurrence of partial neurasthenia and prodromata of apoplexy also suggest the possibility that some minor nervous symptoms, spinal or otherwise, are possibly due to malnutrition of the brain from arterial disease. It is not sufficient to make a diagnosis of spinal neurasthenia in some of these cases; the possible underlying cause, endarteritis, etc., must also be considered. The various forms of neurasthenia may also be brought under this same etiologic category. He would not say that all nervous affections are due to this cause, but very many have it for a factor, and it should receive more attention in the management of these cases. The treatment of neurasthenia, neuralgia, spinal and hemiplegic symptoms also includes methods which have for their aim the establishment of an equable circulation. The ordinary treatment of arterial sclerosis by drugs he does not

consider very satisfactory. There is usually very great variation in the tension of the pulse, and while we can control this with various remedies, it is improper to keep such constantly employed. He has never observed in the treatment of Graves' disease a high-tension pulse. He thinks the thyroid secretion in the blood is responsible for this. This suggests the use of thyroid extract in the conditions of arterial disease. He has found it of great benefit in managing temporary high pressures, and has also seen a certain amount of benefit from its use in chronic conditions, for which he prefers it to nitroglycerin. It should not be overlooked that many patients who have extensive arterial disease, with its symptoms, live to extreme old age, and this should be remembered in making the prognosis. Many persons also having the physical signs of extreme arterial sclerosis have no symptoms whatever. The underlying condition is one that may spontaneously subside or disappear under treatment.

2. **Portal Anastomosis.**—Floyd's article gives a description of the liver circulation in the fetus at term, the changes following at birth and the sites of anastomosis between the portal and systemic veins in the adult. The article is detailed and contains several schematic diagrams which aid in its comprehension.

3. **Uric Acid.**—Croftan has investigated the effect of uric acid injected into the system and how it is destroyed. His clinical conclusions are stated at some length. He finds that the watery extracts prepared from the kidney, liver, muscles, blood and spleen all destroy uric acid in varying degrees, and it is probable that these organs have the same effect during life by the aid of unorganized soluble ferments secreted. The proposition that uric acid is normally destroyed in the organism may therefore be considered answered in the affirmative by these experiments, and from analogy with certain animal experiments. Bulk for bulk, the kidney destroys more uric acid than the liver, the liver more than the muscles, the muscles more than the spleen and the blood. The fact that the kidneys normally destroy uric acid teaches that great care should be exercised in drawing conclusions from the plus or minus of the urinary uric acid excretion. The circulating urinary uric acid can not be considered as an index. It merely represents the algebraic sum of circulating uric acid and the uric acid destroyed in the kidneys. There is, therefore, always more of circulating uric acid than is indicated by the urinary uric acid excretion. Derangement of the liver function has been considered as a cause of uratic diathesis, more uric acid than normal being formed. It seems to Croftan that the derangement consists in inability of the liver to destroy the normal amount of circulating uric acid or the excess that is so frequently ingested. The power of the muscles to destroy uric acid may explain, as Wiener suggests, why exercise often relieves uratic symptoms. The accelerating effect of salicylates and dilute alkalies on the power of one of the uric-acid destroying bodies (the nucleo-proteid) to liberate oxygen, aids in explaining why these remedies are beneficial. The formation of oxalic acid from uric acid in the kidney may explain the clinical fact that in gout oxaluria is not infrequent, and occasionally the appearance of much oxalic acid in the urine is accompanied by a corresponding decrease in the uric acid. The formation of urea from uric acid demonstrates that uric acid is not a terminal product, but an intermediate one between certain albumins and urea—the old view slightly modified. Much that has been written on the urea-uric acid ratio is sheer nonsense. There is much experimental evidence to show that the function of certain organs that destroy uric acid is also to destroy fats and sugars. Inadequacy of this triple function would lead to the accumulation of fat, of sugar and of uric acid, pointing to the pathogenic relationship between obesity, diabetes and the uratic diathesis, all characterized by accumulations in the blood and tissues of bodies that should normally be destroyed.

5. **Tent Life for Consumptives.**—Stubbert insists on the value of tent life giving free ventilation which can not be supplied in the winter by sleeping with the windows open, excepting in very exceptional cases where the room has a southern exposure and there are windows on three sides. Tent life furnishes the conditions needed and should be made as comfortable as possible. For the summer months hardly anything more than a sheltering roof will be required, but in the winter in the colder regions something more substantial is needed, such as a conical tent with perfect ventilation in all kinds of weather. He advocates the erection of tents in connection with hotels and summer resorts. The great value of the open-air treatment is its cheapness combined with its demonstrated efficacy. The best site for a tent is not in a forest, but on the edge of a wood where the patient can have the full benefit of sunshine and free circulation, with shade within reach and protection from the colder winds.

12 The Medical Institutions of Madrid. Nicholas Senn.

6. **Painful Affections of the Feet.**—The frequency and severity of affections of the feet among trained nurses have been studied by Lovett, who details his methods of treatment and offers his conclusions as follows:

1. It has not been possible to tell, with any certainty, by examination whether or not the feet of an individual are likely to give trouble. The only reliable information obtained in these cases was given by the imprints seen through glass. A foot with a well-distributed pressure area seemed rather less likely to give trouble than one resting on two islands; the degree of pronation, the condition of the circulation, the relative weight of the nurse, and the dorsal flexibility of the foot all proving of little or no value as elements in prognosis. A flat foot may be perfectly serviceable, as may also a severely pronated one, while an apparently well-balanced foot may become painful.

2. The factors in causing the trouble among the nurses were to be sought rather in the general conditions than in any special conformation of the foot. It followed, in many cases, illness and other conditions causing muscular debility. It occurred in most cases from two to three months after entrance, and it began most often in the early spring, when the nurses had been indoors all winter, and least often in the fall.

3. The trouble was caused by a rolling in of the foot and a shifting inward of its weight-bearing areas and not in any case observed by a breaking down or even lowering of the arch.

4. Although proof by figures is lacking, it is probable that the amount of trouble has been decidedly less than it would have been without the use of a proper boot.

7. **Why Glasses Do Not Give Relief.**—It is naturally impossible to detail all of the sixty-eight reasons with their bases as here given by Gould. He emphasizes, however, the defects of the physician in refraction work, which he claims requires a special adaptability, perfection of methods and appliance, care in determining the relative amounts of astigmatism, etc., and the proper methods of examination. The necessity of wearing the right kind of glasses and seeing that they are properly adjusted are emphasized. For further details the reader is referred to the article.

8. **Funnel-Chest.**—Two cases are reported by Richards, one of which was extreme. This form in which the entire sternum is depressed is rare. There is always a congenital deformity and treatment is practically unavailing.

9. **Pregnancy.**—The most important signs of early pregnancy, according to Williams, are change in the shape of the uterus from the pyriform to more spherical shape, the softening of the lower uterine segment, which is not always reliable, the bluish discoloration of the vagina, which he thinks is of considerable value, the lowered cervix and the increase in the weight of the uterus and its lessened mobility. In conclusion some remarks are made on the recognition of ectopic pregnancy.

10. **Tonsillotomy.**—The point of interest in the case reported by Urban is that complete exsanguination resulted from tonsillar hemorrhage following tonsillotomy, bleeding from the nose, lungs and stomach being excluded by careful examination. The occurrence of such severe bleeding in children is rare, and there was here probably an anomalous tonsillar or internal maxillary artery. The case indicates that one should be prepared for such complications.

20 Septic Endocarditis. A. W. Dudley.

13 and 17.—**Surgical Tuberculosis.**—Burrell accepts the view that about 80 or 90 per cent. of adults at the age of 40 have been affected in one way or another with tuberculosis. The infection is a universal one. The fatality of the disease, however, is decreasing. The surgical type itself is most frequent between the ages of 10 and 30 years of age according to Leonte. It is clear that the majority of individuals are able to conquer the disease; it is not as malignant in character as has been alleged. He discusses at some length the pathology and the principles of treatment, which are physiologic rest and improvement of the powers of resistance of the individual. Naturally sanatorium treatment is discussed at some length, and he describes the methods and makeshifts which have been utilized, and criticises the ordinary hospital construction in some respects for this disorder.

14. **Typhoid in Children.**—The conclusions of Churchill's article are that the blood in infantile typhoid differs from that of adults only in degree. There is a reduction of the erythrocytes, especially during the first three weeks, with subsequent increase, reaching normal on the fifth week. The hemoglobin suffers more, proportionately, than the erythrocytes. The leucocytes are reduced throughout the first four weeks, the lowest average being reached during the second week excepting in severe cases. Leucopenia is of diagnostic value, especially in children, in whom most febrile affections produce a leucocytosis. We need more data to determine the relative proportion of the different varieties of leucocytes in the different groups, the greatest variation being in the polymorphonuclears and mononuclear elements, the latter increasing and the former diminishing with the disease. The increase in mononuclears is chiefly in the lymphocytes.

15. **Cancer and the X-Rays.**—Van Allen insists on the importance of the selection of apparatus, favoring the use of a coil rather than a static machine; the proper selection of tube; care as to inflicting burns, either on the operator or the subject; the frequency of treatment; the length of exposure, etc. In many cases he finds the combination of removal by cutting and radiation the best course. He briefly mentions other uses of the rays, such as for lupus erythematosus, epilation and pustular eczema of the lip; reporting cases.

18. **Cardiopulmonary Murmur.**—This murmur, which has been considered as indicating some unusual relationship of the heart and lungs, has been found by Putnam to be more frequent among neurasthenics than among other classes. His observation suggests that it is not impossible that it is a disease due to some abnormality or defect of the innervation by which the action of the heart is brought into relation with that of the lung. The explanation of the phenomenon is easier if we assume that the regulator mechanism governing the lung tension or tension of the vessels has been damaged and the relation between the two has become defective. He does not claim this as an adequate explanation, but one that may possibly assist in obtaining a satisfactory one.

21. **Intravascular Antisepsis.**—Barrows defends the use of intravascular antiseptics, claiming that experiments made on rabbits with unfavorable results do not invariably represent the conditions in the human subject. Much stronger solutions of formaldehyd have been used by Jenks of Memphis, Nelson of Virginia and Maguire of London in the treatment of pulmonary tuberculosis, without harm. His own experience has borne out their conclusions, and he is satisfied that one need have no fear of trouble in this direction. His technic is described. A freshly-made 1 in 5,000 solution of formalin (40 per cent. formaldehyd) and freshly prepared normal saline solution at a temperature of 100 is injected into a superficial vein, care being taken to have the nozzle in the vein and that air is prevented from entering. The fluid should be slowly injected, the amount depending somewhat on arterial tension and the general character of the pulse. He reports four cases in this installment of his article, which is to be concluded in a future number.

22. **Appendectomy.**—A simple method here described by Ries consists in freeing the appendix from the mesoappendix down to the cecum, then cutting it off about one-third of an inch from its base, inserting a suture with a round straight needle into the lumen of the stump, passing it out about one-sixteenth of an inch below its end. Then the needle is introduced into the lumen of the stump and carried out through the cecum externally about an inch from the base of the appendix. Traction on this thread inverts the appendix into the cecum and the serous funnel of the inverted appendix is then sutured. The thread which has drawn the appendix into the gut is then cut off close to the surface of the cecum and rubbed into its lumen. The mesentery is then sutured in such a way that its stump covers the suture of the appendix so that no raw surface or foreign body remains in the peritoneal cavity except the last knot of the catgut. The perforation of the bowel by a needle is, he claims, perfectly harmless. It is completely closed by rolling the bowel between the fingers. Another possible objection is that the inversion would be impossible where there is a stricture or obliteration of the appendix. This, however, might be overcome by simple perforation of the obliteration or stretching of the stricture. He has never had any trouble as a consequence of the use of this method, which he prefers to others, and has employed in 21 cases. The whole operation takes less time to perform than to describe it, as can be seen by three cuts.

24.—See abstract in THE JOURNAL, xl, p. 1602.

25. **Perineal Partial Prostatectomy.**—Van Hook operates somewhat on the plan of Zuckerkandl, making a transverse incision in the perineum about an inch in front of the anus, not over an inch to an inch and a quarter in length. He then makes a median incision into the membranous portion of the urethra, in this respect differing from Zuckerkandl, who continues the transverse cuts. The point of the knife, under the guidance of the finger, is introduced into the urethra and into the groove of the staff and pushed forward. An opening of the desired size is made, usually about three-fourths of an inch in length. The bladder is then completely explored with the finger, and it is always necessary to empty it to do this thoroughly, and possibly to have an assistant push it down from above. Next the prostate, the median and lateral lobes are carefully examined, which can be better done with the finger within the bladder than in any other way. Next the finger is removed from the urethral wound, and the lateral lobes are palpated through the capsule, passing the finger outside the urethra between the lateral halves of the levator ani until the commissure of the prostate is reached, when the finger is passed over each lateral lobe in succession. Usually the right half of the prostate is first operated on. It may be necessary to cut the capsule enough to facilitate penetration of the prostate with the finger. The finger is then swept around the main mass of prostatic tissue, the operator

keeping his mind on the preservation of the capsule. The masses which have been loosened are removed with a stone forceps or the hysterectomy volsella forceps of Richelot. It may be necessary to draw down the uppermost part a little with the tenaculum forceps. The left half can generally be removed in the same manner and the median lobe can almost invariably be removed without opening into the bladder. In case of excessive fibrous character of the mass, making the enucleation process of the finger difficult, Van Hook has devised a sort of scissors-like instrument for morcellating the organ. It is only a matter of convenience to use this, as curved scissors can also be used. Having removed as much of the prostate as seems necessary, he introduces a drainage tube into the bladder about the size of a finger, suturing it to the skin of the perineal wound. Two strips of gauze, one on each side of the tube, are then inserted into the space previously occupied by the lateral lobes. The after-treatment is important. The gauze strips are left for twenty-four to thirty-six hours, care being taken not to disturb the drainage tube in removing them. The drainage tube is left for a much longer period, three or four days to two weeks. A smaller tube may be substituted for a time. The fistula is usually a little slow to heal, but if sounds are introduced twice a week, and if exuberant granulations are kept down by passing a probe armed with silver nitrate along the fistula, there is no difficulty about the eventual closing. The patient should not be required to lie continuously on his back, but after the first twenty-four hours should be turned from side to side, thus facilitating closure of the wound. He thinks the advantage of this partial prostatectomy is that we are less liable to do damage to the other structures. From his experience he thinks the anterior parts of the gland may be easily left, but further experience may be required to decide how much to leave. Probably a diminution in the size of the remainder of the prostate may be anticipated after partial intracapsular prostatectomy. Usually the lateral and posterior parts of the gland are the cause of the trouble, and operation may be reasonably confined to them. He reports a number of cases illustrating the success of the operation.

26. **Diabetic Gangrene.**—Lilienthal divides these cases into three groups according to their urinary and symptomatic indications: Group 1, general condition good; no acid intoxication; sugar much or little; one or two toes or fingers affected with or without phlegmon, but not threatening usefulness of the member. In these cases the treatment should be conservative, the affected fingers and toes removed and the plegmon drained by the freest incision and the wounds packed; wet dressings applied, tendon and fascia being allowed to slough away. Group 2, general condition good; no acetone or diacetic acid in the urine. Local condition threatening the usefulness of the member. Here the ablation of the limb high above the upper level of the disease is the proper course. If the disease is in the foot, it is best to make the amputation well above the knee. In the upper extremity, however, amputation need not be above the elbow for gangrene of the hand. Skin and muscle flaps instead of mere skin flaps should be used. Group 3, general condition poor or comparatively good. Much or little sugar; acid poisoning present. Disease threatening or not threatening the part. In these cases treatment must be palliative until the acid poisoning and its impending coma shall have disappeared. If this can not be brought about, the prognosis is poor and should deter us from radical operation. This does not mean, of course, that drainage should not be used. On the contrary, free incision of the tissues impeding free evacuation of the phlegmonous spaces must be practiced in any event, but no more than is absolutely necessary should be done, and no radical operation. He remarks on the change in treatment that this form of gangrene has undergone within the last fifteen years owing to our more improved clinical methods of testing the urine for acetone, acetoacetic acid and total ammonia.

27. **Proctitis.**—Two cases are reported by Bray and discussed. He insists on the importance of digital examination in case of chronic diarrhea which will detect polyps, ulceration and impactions. The next in importance is the use of the procto scope. With it in a proper light the entire circumference of the bowel can be seen. He puts the patient in the Sims position, oils the tube and slips it through the sphincter while the patient is straining. When it has been introduced about three inches in the bowel, atmospheric inflation will lift the walls out of contact, and the direction of the tube can be observed as it is passed up in the sigmoid flexure. When fully introduced it is gradually withdrawn and the whole gut thoroughly examined. It is important that the diagnosis should be made early for proper remedial measures to be employed. The first thing to do is to remove the cause. The local treatment consists in antiseptic and astringent injections. If there is any local disease, this, of course, should be first attended to.

28. **Drainage in Empyema.**—Lile describes a new drainage tube of hard rubber with a cup-shaped funnel on each end, bent at an angle a little greater than a right angle. The short arm is inserted into the pleural cavity. The longer arm is flattened to hold it in place. It can not slip either in or out and drains perfectly. Irrigation can be done through it with perfect ease. With this drainage tube he sees no reason for resection of the ribs, excepting in cases with sinuses existing for months after removal of the tubes, or in certain tuberculous cases.

30. **Tuberculosis.**—Maragliano's article has already been reviewed at some length in these colums, p. 67.

31. **Tuberculosis in the Tenements.**—The suggestion made by Meyer is that the fire escapes be utilized for the open-air treatment of tuberculosis in tenement houses, and he gives illustrations. There is one difficulty in the way, and that is the section of the building code which prohibits placing encumbrances on any of the fire escapes, but he thinks this is practically disregarded. He believes that public opinion will justify the use of fire escapes for the preservation of life from the ravages of tuberculosis. They are available in most tenement houses in the large cities. He points out their advantages in the way of open-air, shelter, or the easy possibility of such, etc.

35. **Problems of Tuberculosis.**—Heffron notes the overthrow of the importance of heredity in tuberculosis, the importance of infection and the remedial value of producing a soil that is resistant. He says the decrease of tuberculosis has been very marked and, as regards bovine infection, he holds that the burden of proof is on Koch's side and he will be required to show to the perfect satisfaction of others that infants are never infected by the use of milk of tuberculous cows. The diagnosis of tuberculosis is practically impossible in its incipient stages. The fact is that most persons have probably suffered from it to some degree, and he does not see how we can escape the view of Welch that with proper search almost universal infection must be admitted. As regards the methods of diagnosis, he thinks accurate thermometry is one of the most important, while the tuberculin test is also reliable if properly used, and is not injurious. The present status of prognosis shows a marked change from twenty years ago. Throughout the world the number of deaths from tuberculosis is decreasing, England heading the list. The percentage of cures in the various sanitariums and so on shows the tractability of the disease under proper care. The prognosis is better the earlier the disease is recognized. The immunity question is noted, but Heffron is not prepared to admit that immunizing injections can yet be safely used on man. In the treatment there are certain general principles: faith in the

curability of the disease, and not so much the attack on the bacillus as the strengthening of its host by open-air treatment, etc. Recoveries from tuberculosis are far more frequent than those from insanity, as he shows by comparative statistics.

46 A Plea for the Removal of a Minimum Amount of the Board Ligament in Salpingo-oophorectomy. J. Wesey Bovée.
47 *The Vaginal Incision in Sepsis Following Abortion. Hunter Robb.

43. Chronic Inversion of the Uterus.—Peterson describes a case operated on by the vaginal method, splitting the uterus and replacing it. He asks why, in cases of chronic inversion with our present knowledge, we should not in any given case disregard the old methods of reposition and at once employ the more modern, safer and surer surgical methods. The elastic pressure method is uncertain and dangerous and may increase hemorrhage, which the patient can not afford. The same is true to a greater degree of taxis. This is not the less true because of the fact that spontaneous reposition has taken place. The safest way is some form of incision operation by the vaginal route.

44. Hysterectomy for Fibroids.—The position held by Keith is a conservative one in the main. It is impossible to lay down positive rules for hysterectomy. The age of the patient, surroundings, etc., should be considered. In the following cases, however, he says we can safely say that hysterectomy ought to be the rule. In all fibro-cysts, in all edematous tumors when accompanied by profuse watery discharge, in large tumors causing symptoms; that is those reaching up to the ribs, and when the patient is under 50 years of age, and even over that age, it may be worth while to have a large tumor removed. In small tumors extending not higher than the umbilicus, fibro-cysts and edematous tumors excepted, he would advise the Apostoli treatment which he has, in fifteen years' experience, found to be valuable in reducing the growth, and causing early menopause in the great majority of cases of fibroids where the growth is not submucous, without danger to the patient. He does not hold that electricity, even in case of small tumors, is always the best treatment, because the risk of hysterectomy is so slight.

47. Vaginal Incision in Postabortive Sepsis.—Robb finds that in the majority of cases the infection begins in or near the external genitals, successively implicating the vagina and cervix, the uterus and fallopian tubes and finally reaching the peritoneal cavity. His method of treating these cases is to dilate the cervix, curette the uterus either with the finger or finger and curette combined, wash it out with hot saline solution and 2 ounces of peroxid of hydrogen, then cleanse again with hot saline solution and sponge dry. Two or three drams of iodoform powder are then carried into the cavity, and it is packed with strips of sterile gauze. He then makes a free opening into the cul-de-sac, and after evacuating any fluid that may be present, irrigates it freely in the same way as has been done with the uterus. Then two or three drams of sterile iodoform powder are dusted in the cul-de-sac, which is filled with strips of sterile gauze. By this method he claims that we prevent future absorption of toxins from the cul-de-sac, save the fallopian tubes and ovaries by preventing adhesions which would almost inevitably form as a result of the organization of the exudate. He gives in conclusion the bacteriologic and clinical history of 10 cases of septic infection thus treated.

48 *Nephritis, Its Diagnosis, Particularly of Atypical Forms, and Some Points in Its Treatment. Arthur R. Edwards.
49. *The Moist Dressing in the Treatment of Compound Fractures. Charles H. Lemon.
50 A Case of Bromoderma Pustulo-Tuberosum. M. Milton Portis.

48. Nephritis.—The chief conclusions of Edwards' article are given in substance as follows: Carefully repeated routine chemical and microscopical examination of the urine every twenty-four hours usually, but not invariably, detects acute and chronic nephritis, if aided by examination of other viscera and parts, such as disclosure of cardiovascular changes, retinal involvement, etc. The visceral or somatic changes, usually present in nephritis, may be lacking in such cases and be capable of other interpretation, such as polyuria, atheroma, etc. The most essential urinary findings may be lacking and we may still suspect nephritis, even after negative results. Nephritis may be unattended by albuminuria. It is then usually interstitial in type, though chronic parenchymatous nephritis, acute nephritis and chronic interstitial nephritis, as well as the type described by Dr. D. D. Stewart, may also occasionally occur. Casts should always be searched for. They sometimes seem to indicate a degeneration rather than an inflammation, and are not invariable in nephritis nor are they invariably nephritic. Further clinical caution and pathologic examination will probably increase the number of cases of non-albuminuric renal inflammation of acute, subacute and chronic types. The non-albuminuric nephritis of the Stewart type is of special importance in life insurance and in practice, since prophylactic measures may be instituted and the prognosis affected. Uremia may be easily confused with organic brain lesions, and vice versa. Every type of focal brain lesion is simulated, and it may, moreover, coexist with brain disease. In treatment rest to spare the kidneys and save the heart is of prime importance. Rest applies to nervous strain as well as to physical work. The diet should not irritate or tax the kidneys in its elimination Nutrition requires individual study; the classic diet must be abandoned when there is loss of weight or increasing anemia. Edema is poorly managed by diuretics; cathartics too often threaten assimilation and nutrition; sweats tend to concentrate the blood and rather favor uremia. Mechanical drainage is the best procedure, since it removes not only the fluid, but the contained impurities, avoiding their repassage through the already surcharged blood and damaged kidneys. The condition of the heart and the efficiency of response to cardiants is often the main thing in the prognosis and treatment.

49. Moist Dressings in Compound Fractures.—The moist dressings here described by Lemon consist in the application of hygroscopic gauze moistened or wrung out of water or an antiseptic solution, and applied to the skin or wound surface, its evaporation and consequent drying prevented by its being covered with some impervious material like oiled silk or gutta-percha tissue. Its hygroscopic character promotes absorption of the wound secretion, distributes it evenly and prevents its accumulation in the wound. It stimulates the regional capillary circulation in the cut surfaces and induces a vigorous blood current which mechanically washes out the wound and brings an abundance of blood tissue to the threatened area, the best antiseptic, provided the infective material is not too excessive. In treating compound fracture he would introduce a bit of gauze or some strands of catgut through the wound for a drain. Such a wound properly treated has no swollen or everted edges, no redness, no sloughing surfaces, no tension,

pain or fever. This is the ideal result. If we know that infection is absolutely absent a dry dressing would be better, but we can not be sure. Illustrative cases are given.

56 Clinical Report of a Case of Typhoid Fever in a Seven-Months-Old Infant. A. W. Clouse.
57 A Case of Gastric Crisis of Tabes. Frank H. Murdoch.

51. **Tonsillectomy.**—Lautenbach holds that enlarged tonsils are always a menace to health, and unless there are unusual complications, should be removed. The operation is not difficult and seldom has serious results. It is attended with increased health, better respiration and improved digestive function; there is less liability to microbic disease, especially diphtheria, and the nasal catarrh will be improved. The lymphoid structures in the pharynx will disappear; the tendency to ear disease is diminished and there will be no more tonsillitis.

52. **Radiotherapy.**—Johnston holds that there is only one way to become a good radiotherapeutist, and that is by experience. Every tube must be studied by itself. It should be seasoned by a course of radiographic work before it is used for treatment. The same tube acts very differently under different circumstances. After a man has used one for a while he learns its peculiarities. The low vacuum is more dangerous in inexperienced hands, but the hard tube is not much safer. It is not necessary to burn the patient, and if proper dosage or suitable radiation has been administered the healthy tissues suffer very little. The pathologic tissues, however, slough or are absorbed. The danger of desquamative dermatitis is an ever-present one whenever radioscopic inflammation exists. We must be especially careful in operating around the tongue, pharynx and lips on account of the difficulty of giving outside drainage and danger of swallowing of the irritating secretions. The cumulative action, with the long period of incubation, must not be lost sight of, and idiosyncrasy should be considered. The so-called strawberry blondes are peculiarly susceptible to *x*-ray burns or dermatitis. He claims that treatment, with proper management and skill, of the various forms of skin lesion is very satisfactory, but the man who wishes to apply it should study his apparatus and his patients and select them carefully. He should avoid routine measures.

61 *A Discussion on the Differential Diagnosis and the Treatment of Osteosclerosis of the Mastoid Process. Otto J. Stein.
62 Three Cases of Encephalitis in Connection with Otitis Media. Dr. Voss.

58. **Depth of the Mastoid Antrum.**—From measurements and facts adduced, Kerrison thinks we are justified in saying that in operations on the mastoid process the antrum should be approached from the nearest point of the mastoid cortex which, in the great majority of cases, is a small triangular space just behind the spine of Henle. This point of attack not only furnishes a guide to the site of the antrum, but also affords fairly accurate data in regard to the depth beyond which it is not safe to proceed. The depth of the antrum is always less than the length of the postero-superior wall of the meatus; in the great majority of bones it is not over 12 mm., is often very much less, and never greater than 15 mm., or ⅝ of an inch. Therefore, in surgical attempts to expose the antrum, ⅝ of an inch should be regarded as the extreme limit of safety.

61. **Mastoid Osteosclerosis.**—The diagnosis of this condition is discussed by Stein, who quotes largely from authorities. He points out the possible differentiation from hysteria and neuralgias from other causes, such as syphilis, reflexes from diseased teeth, nasal and laryngeal disorders, etc. In hysteria we have the characteristic mental condition and symptoms. Pain is more frequently located in the auditory canal, and is also referred to the temples. It is greatly affected by the mental condition. The history, heredity, etc., should also be considered. In syphilis the history of infection and the characteristic nocturnal pains are usually sufficient. The pain of neuralgia shoots in the direction of the nerve trunk and its branches. The symptoms of osteosclerosis are largely centralized throughout in pain. There may be nothing objective whatever to be noticed, though we may discover a slight redness and edema and possibly a spot on the line of the meatus that elicits a sharp sensation of pain. The pain is continuous, lasting over long periods with only remissions, and very seldom intermissions and with frequent exacerbations. There may be some rise of temperature in the early stage and deafness. The fact, however, that this nagging, constant pain may develop a neurotic disorder should not be forgotten. While local treatment, such as rubefacients, etc., may be employed in the early stage, surgical treatment is the important part of the therapeutics and authorities seem to agree as to its benefits. In operating, the object is to relieve the bone tension, and we should remove as large a core of bone as possible with clean, smooth edges and surface. In conclusion, he urges the recognition of a broader field for surgical intervention in affections of the temporal bone.

67 Sewage Disposal for Inland Towns. Arthur N. Talbot.
68 Successful Removal of a Cystic Fibro-myoma of the Uterus Weighing 87 Pounds. J. Clarence Webster.

64. **Bacteriologic Examinations.**—Hektoen points out the advantages of bacteriologic examination of the blood during life, and describes the technic, the making of cultures, etc., and reports instances of its value. His conclusions are that bacteriologic examination of the blood by modern methods has proved of scientific and practical value in septic diseases, in septicemia, in pneumonia, and especially in typhoid and paratyphoid fevers. The etiologic diagnosis, that is, recognition of the exact disease, requires the application of practical medicine or laboratory methods, which, however, will be more and more facilitated for private use by the physician in his office.

66. **Diplococcus Scarlatinae.**—Class argues for the characteristic value of the diplococcus, which he says usually appears as a very large diplococcus, at least four times as large as the ordinary staphylococcus. It occurs in about 90 per cent. of cultures if made early in scarlatina, and can, as a rule, be easily differentiated from other large cocci. It may happen, however, that we may have cultures on blood serum giving but small staphylococci. The negative result is due either to the change of form of the germ or that it does not take the stain. These difficulties will seldom occur with his earth agar. It is also a good plan when primary cultures fail to show the typical diplococcus to isolate the germs in cultures by means of the plate method when the cultural characteristics of the organism, such as its glutinous character, and the fact that it does not affect milk in its growth, will prove of great aid in its recognition.

71 The Treatment of Stricture of the Anterior Urethra. W. L. Champion.
72 Medical Jurisprudence. James R. Cain.

69. **Uncinariasis.**—Harris gives an account of this disorder as it occurs in Georgia, especially in the towns along the Georgia Southern and Florida Railway. His findings agree with those of Stiles. He notices the difference between the disease

when due to American and the old world species, the lack of petechial spots, etc., and suggests that the *duodenale* type may be the more severe form of infection. He has never found Charcot-Leyden crystals with the eggs, though they are said to be invariably found in the stools of those affected with the European malady. No disease so grave as this can be cured with such rapidity and certainty. He has never seen a case where complete expulsion of worms was not secured if the patient followed directions as regards not eating the day before, the use of free purgation and the taking of 60 gr. of finely powdered thymol. Alcohol should be avoided. Beyond this it is hardly necessary to do anything further, though there is no harm in giving tonics.

76 *Report of 53 Cases of Typhoid Fever, Treated in the Medical Wards of the Presbyterian Hospital, in Which Acetozone Was Used During November and December, 1902, and January, 1903. D. Flavel Woods and M. C. Thrush.
77 Iodoform Substitutes and Adulteration. V. Coblentz.
78 The Physiologic Action of Adrenalin Chlorid. Isaac Ott and S. B. Harris.

75. **Hyoscin in Morphinism.**—Crothers condemns the use of hyoscin as an antidote for morphinism. He thinks the withdrawal of one narcotic and the substitution of another can never bring about a cure, and is a very doubtful measure, and that further experience will sustain this opinion.

76. **Acetozone in Typhoid.**—From the results of 53 cases here tabulated, Woods and Thrush conclude that acetozone is a valuable intestinal antiseptic, apparently lessening the tendency to tympanites and diarrhea, especially when given early and continued until convalescence is well established. The stools seem less offensive, and in most cases the color and consistency are not affected by its administration. The drug does not seem to act on the heart or respiratory organs or have any appreciable effect on the kidneys, and hyperpyrexia rarely appears when it is used. Relapses are also infrequent if it is properly employed until well into convalescence. All the cases here reported gave the positive Widal reaction and other clinical symptoms.

79.—See abstract in THE JOURNAL, xl, p. 1669.

80. **Myositis Ossificans.**—There are two types of this condition, one where bone has formed in the softer tissues, with or without history of injury, and no apparent connection with the skeletal bones or their periosteum, or where osteophytes occur to which muscle tissue is attached and which has undergone osseous change. The second is where there is formation of new bone resulting directly from accident to the bone or its periosteum, and involving the muscles and fibrous structures. A number of cases have been reported like this where the muscles became quickly ossified after injury. Several of these are reviewed in brief. The author then reports his own case in which a man was kicked by a horse in the thigh, producing periosteitis and the muscles—especially the deeper fibers—contained small bony particles. The pieces of bone and muscle tissue that were here removed were directly in contact with the periosteum. The patient made an uneventful recovery. The second case was more on the first type, a gradually developing formation of irregular bone plates growing from the fibula.

81. **Bone Aneurisms.**—This term has been applied to certain obscure, pulsating hemorrhagic tumors of the bone which are considered a specific affection by Oehler. Gaylord reviews the five classical cases noticed by Richet and Volkmann, and some more recently reported ones by Anger, Wythe and Oehler. He follows these with a report of his own case, with microscopic findings. He concludes that the affection can hardly be considered a specific one and that in all probably the greater portion, if not all, of the cases of bone aneurism were originally medullary sarcomata. He agrees with Gentilhomme that while these tumors may have the characteristics of aneurisms, their etiology and the mechanism of their development are quite different. The question, therefore, to be decided is whether the term "bone aneurism" should be continued in the literature or whether we should refer to these cases as pulsating sarcomatous hematoma of bone.

83. **Resection of the Fifth Nerve by the Orbital Route.**—Cook gives in detail the method used for resecting the second branch of the fifth nerve at the foramen rotundum, bringing the distal end to between the alveolus and the upper lip, thus three inches away from the proximal end and turned in another direction, devised by Dr. Melancthon Storrs. The description of the operation is given as follows: The patient is put half reclining in a rocking chair, wedged with sand bags. One assistant is necessary to give the anesthetic and a second to hold the retractor.

> The lower edge of the orbit can easily be felt through the skin. Make a clean incision along this edge, from the inner to the outer angle of the orbit, through the tissues, including the periosteum, down to the bone. Then, with a blunt instrument, carefully elevate the periosteum from the floor of the orbit, going well back and exposing the sphenomaxillary fissure. Lift the eyeball out of the way with a spoon-shaped retractor inserted under the periosteum. Usually a bluish spot will appear, showing the situation of the infra-orbital nerve, covered by a thin plate of bone, in its canal in the floor of the orbit. Should there be any difficulty in locating the nerve, it can easily be done by passing a probe into the infra-orbital foramen and up into the orbit. Having located the nerve, with a chisel or any suitable instrument, crush the thin plate of bone covering it. The nerve can then be easily hooked up and brought into view. The infra-orbital artery is usually torn at this time, and bleeds for a few moments; but it is of no importance and will soon take care of itself. Having hooked up the nerve, ligate it securely with a piece of silk passed around it with an aneurism needle. Then cut the nerve, leaving the ligature fastened to the proximal end of the cut nerve. We now have the nerve under perfect control. By making a slight traction on the ligature we can bring the nerve into view, and by following it on can readily crush down the thin wall of the canal, removing the bone fragments with suitable forceps. When the nerve enters the sphenomaxillary fissure, it passes out of the bony canal, and is only surrounded by soft structures, which can easily be hooked or wiped away. Should the sphenomaxillary fissure be narrow, and not readily admit the introduction of instruments, it can easily be widened by inserting a suitable blunt instrument and by wedging or widening the walls. It is remembered that the upper wall of this fissure is the strong wing of the sphenoid bone, and that the lower angle is the thin wall of the antrum. If either bone should break in these manipulations, it would be the wall of the antrum which would be crushed down and out of the way, and would cause no trouble. Having the nerve thus free to the foramen rotundum, next slip the ends of the silk ligature through a loop of wire, held with a small snare (the Jarvis snare of the rhinologists). The loop of wire in the snare is passed down the nerve to the foramen rotundum, just as a tunnel sound is passed over a filiform bougie. When the loop of wire reaches the foramen rotundum it is closed, and the nerve is cut and removed. To return now to the distal end of the nerve. Separate the integument from the bone down to the infra-orbital foramen, gather up with a hook the mesh of nerves going to the cheek, and drag the divided nerve through the foramen. Storrs then puts the nerve into the loop of a threaded needle and carries it down into the mouth, leaving the end which has been in the infra-orbital canal suspended between the alveolus and the upper lip; this end he cuts off even with the mucous membrane. This was for the purpose of preventing any possible restoration of any communication between the peripheral branches of the nerve and the stump left at the foramen rotundum. To complete the operation, place a small gutta-percha tissue drain in the track of the nerve, extending from near the foramen rotundum to the surface. Suture the skin wound. The drain should be removed at the end of twenty-four hours.

He says the operation is very simple and can be performed on elderly and feeble people with but little shock. Relief is immediate in all cases and permanent cure is effected in many. Scarring is insignificant and the patient is not long confined.

85. **Drowning by Fecal Vomit.**—Andrews reports two cases in which he thinks this accident occurred. The conclusions are given as follows:

1. Flooding of the air passages by fecal vomit is a real danger, and probably has caused many unexplained deaths. 2. Resuscitation is impossible or very difficult. 3. The fluid may flow by gravity through the relaxed stomach sphincters directly out of the intestine where it has accumulated in enormous quantities. 4. The accident occurs with great suddenness and with a stomach supposedly empty. The suffocation may be so complete that no outcry is made and may not be noticed by the attendant. 5. It may occur as late as an hour after anesthesia, or at any time until consciousness is restored. 6. We have no evidence that it can occur during consciousness even in extremis. 7. After septic laparotomy, patients, when returned to bed, should be watched, without even momentary intervals, to full consciousness. 8. A suggestion made to me by Dr. McArthur that as many as possible of such cases be operated under cocain anesthesia, seems to me sound in the light of the above report.

86. **Splenic Infections.**—Stavely reports two cases; in one he considers the diagnosis of splenic abscess with perforation of the kidney and discharge of pus *per urethram*. The abscess was opened, but full exploration was not attempted. It was irrigated with salt solution and closed. The patient recovered with a small sinus. The second case was one where a diagnosis was made of displacement of the spleen, malarial hypertrophy, hemorrhage, suppurative perisplenitis, infective splenitis, thrombosis of the splenic vessels and infarction. The spleen was removed, and found greatly enlarged, soft and friable and densely engorged. The parenchyma and retiform spaces of the organs were infiltrated and greatly distended with blood extravasation and with some hypertrophy of the retiform framework. Cultures from the organ yielded growths of the *Staphylococcus pyogenes albus* and *Bacillus coli communis*.

87. **Typhoidal Gall-Bladder Perforation.**—Erdmann reports the case of a woman, 46 years of age, on whom cholecystectomy was performed, and adds 3 more to those already collected by Keen and analyzes them. All the cases that recovered were operated ones; 4 out of 7. The diagnosis depends on a careful and thorough study of the cases, stress being placed on the original site of pain, and bearing in mind that pain in this region may come from perforating ulcer of the stomach at its duodenal end, or from the duodenum itself or the gall-bladder, and it may be also the pain of acute pancreatitis. The only treatment is operative. He prefers incision through the rectus muscle rather than at its outer border, or in the median line, as this gives the best exposure and the least possibility of hernia. Cholecystectomy is the only thing to do; the friability of the tissues is against the repair of the perforation. In the 2 fatal cases, the operations were incomplete, leaving only one in the 5 fatal cases where complete operation was done.

90. **Primary Carcinoma of the Appendix.**—From his study of the signs, symptoms and anamnestic data, Moschcowitz concludes that we can not give an exact estimate of the frequency of the condition. It is rare as compared with inflammatory disorders of the appendix, but so many new cases have been reported during the last few years that we may have to modify our opinion as to its extreme rarity. Apparently all primary carcinomata begin in the mucosa and it is probable that they take their origin in some preceding inflammatory process. The disease is most frequent at the time of life in which inflammatory diseases of the appendix are most common. This accounts for the early age of the cases reported. It is more frequent in the female than in the male sex, the statistics being about three to one. If it is proved true that primary carcinoma of the appendix originates in prior inflammatory processes, it will be an additional argument in favor of the removal of the appendix when once diseased.

8 Potassium Permanganate in the Treatment of Lupus. J. Hall-Edwards.

3. New Growths.—The points of Monsarrat's article are summarized by him as follows:

1. Cell activity and cell type must always be the resultant of bio-chemical reaction of the principles of which the researches of Ehrlich and others have enabled us to obtain some information. 2. Cell proliferation as a form of cellular activity is always the resultant of such reaction. When it takes place as the result of increased availability of normal food material, the new cells produced conform to the type of the parent cells. When it follows the action of assimilable materials of abnormal constitution new cell types are evoked, variants on the type of the parent cells. 3. Cell proliferation of the latter type takes place in certain microparasitic infections. 4. The new cell types thus evoked exhibit various degrees of instability. 5. In the granulomata (Infectionsgeschwülste) their stability is considerable; in certain growths which result from infective agents (for example, condyloma) the equilibrium of the new type appears to be stable. 6. In the so-called true tumors, cell types arise as variants on the normal cells of the organ or tissue of origin. The ways in which such cell variants may be evoked is not discussed, but that they may result in some cases from the action of micro-parasites is a reasonable view. 7. These cell types are stable; their stability is due to the capacity of the particular variant to attach to itself and assimilate material in conformity with its type. 8. In the simple tumors they are only locally stable, and are not immune to reactionary influences outside the tissue of origin and the normal relationships of parenchyma and connective tissue. 9. In the malignant growths they possess a wide range of stability and immunity, and the degree of this is the measure of their capacity to form metastases, while local infiltration, the other histologic characteristic, is dependent on the principle of chemotaxis, the cells extending in those directions in which their variant and aberrant bio-chemical affinities enable them to annex material conformable to the building up of their characteristic type.

4. Hernia.—Deanesly holds that oblique inguinal hernia is always in a measure congenital, due to a pre-existent patent funicular process. To prove that the sac of any oblique hernia is ever formed by an independent protrusion of the peritoneum unconnected with the processus vaginalis, is absolutely unsupported by any evidence and the only possible proof of it would be the demonstration of the co-existence of an unclosed processus vaginalis with a separate hernial sac alongside of it. This, so far as he knows, has never been demonstrated. The question of congenital or non-congenital origin of ordinary inguinal hernia has, he says, some practical importance. The first deduction is that every case could be certainly cured by the efficient removal of the congenital malformation, that is, the sac—provided the operation is done soon after the first appearance of the hernia or, at any rate, before the presence of the hernia or the pressure of the truss have produced secondary distension or atrophy of the inguinal canal muscles. Delay, therefore, whether the truss is worn or not, increases the difficulty of radical cure. In infants the truss is sometimes an efficient method of treatment, as it enables the patent funicular process to undergo its natural obliteration.

9. Muscular Movements.—The third and fourth lectures of Beevor appear in this issue. The last one discusses the cerebral localization of the various movements, reviewing what has been published from time to time by various authorities, and giving the results of experiments of the author in connection with Sir Victor Horsley in regard to the movements occurring on the same side of the cortex with irritation.

12. The Gruber-Widal Reaction.—From a study of 68 cases of the convalescent type where the Gruber-Widal reaction was tested at various periods after recovery from typhoid, Browne and Crompton find merely 3 cases giving a positive reaction, and one of these only two months after the attack. This is a much smaller proportion of positive reactions than that given by some other authorities, the difference being partly due to the inclusion by authors of cases in which only a few weeks had elapsed from the original attack, and partly to the low dilutions used by them. A dilution of 1 to 10 was first used in all of the authors' cases. When any indication of reaction occurred weaker dilutions were employed. Other observers have used dilutions down to as low as 1 in 2 and 1 in 9. If they themselves had considered, the authors say, a positive reaction of 1 in 10 as sufficient, their list would have shown 8 more positive reactions, bringing their proportion up to 11 out of 68. While they do not doubt that the reaction of low dilution shows that the blood in some cases retains for a long time the specific agglutinative action of the *Bacillus typhosus*, yet they wish to insist that this need lead to no error of diagnosis, provided that sufficiently high dilutions, that is, 1 in 20 or 1 in 50, are proceeded with in cases in which there is any doubt. Their findings agree with those of Elsberg, who sees no relation between the severity of the attack and the duration of the reaction.

13. Pulmonary Tuberculosis.—Dally finds from his studies that the Roentgen rays are an important adjunct to the methods of physical investigation heretofore in use in testing for tuberculosis, and that unilateral limitation of diaphragmatic movement as seen by the fluoroscope is often the earliest indication of incipient disease. He holds that by the aid of the Roentgen rays pulmonary tuberculosis can be diagnosed at an earlier stage than by any other means at our disposal.

18. **Tardy Rachitis and Multiple Chondromata.**—Boinet shows that during the entire course of the growth of the skeleton there are liable to be disturbances in its normal development, involving its various tissues. The changes in the bones regarded as tardy rachitis, whether or not they belong in the category of true rickets of early childhood, should be included in these deviations in development. With them belong also the chondromata that develop in association with these tardy bone lesions. He illustrates a typical, very pronounced case. The incidental cause of the formation of the cartilaginous tumors seemed to have been a traumatism. He also notes that an eruptive fever preceded the appearance of the bone malformations and the swelling of the epiphyses in both this and another case. Consecutive to a fracture of the ankle the right calcaneum in his case became infiltrated with a cartilaginous product and histogenetic troubles rapidly developed, leading to benign gelatinous degeneration.

23. **Syphilis in the Country in Russia.**—Marcou was sent by the French government to study medical conditions in Russia, and expatiates on the differences between syphilis there and in other countries. Outside of the large towns, in which the conditions approximate those in western Europe, throughout the country districts, entire villages and scattered communities are decimated by syphilis, which the habits of the Russian peasants allow to spread rapidly by extra-genital infection. Women and children are peculiarly the victims owing to their promiscuous use of articles, clothing, etc., and their more confined life. The habit of kissing sacred images and acquaintances on certain feast days aids in the dissemination of the virus.

25. **Hepatic Syphilis from Surgical Standpoint.**—Cumston's report of 3 cases and review of the literature is similar to that published previously in this country and recently reviewed in these columns, page 1539.

29. **Tremor Induced by Opotherapy.**—Boinet has observed 10 cases in which tremor was induced by thyroid or suprarenal treatment. Analyzing them, he finds that the tremor is not a sign of intoxication, but merely that the limit dose has been reached. The cases of Addison's disease that exhibited it were the ones most benefited by the opotherapy. The tremor may serve to differentiate this disease and exophthalmic goiter after test of opotherapy.

30. **The Blood in General Paralysis and in Tabes.**—Klippel reports the result of examination of the blood in 31 cases of these affections. The blood count always showed a lack of normal cellular balance. The proportion of polynuclears was increased at first, and later of the lymphocytes, in general paralysis, and in tabes there was also a red anemia and reactional eosinophilia. These facts suggest infection, and are valuable for differentiating dubious cases as general paralysis and possibly tabes may be assumed to be of an infectious nature.

50. **Cardio-Vascular Lesions in Children of Tuberculous Parents.**—The taint in the progenitors, infectious or toxic, especially tuberculosis, entails on the children a liability to congenital hypoplasia of ovular or ontogenetic origin, affecting the tissues which have a common blastodermic origin. When the cardio-vascular apparatus is affected, the lesions are distinguished by the prolonged latency, the consequence of the extreme tolerance of the organism for the lesions to which it seems to have adapted itself before birth. The revelation of their presence comes late, usually on account of some stress which upsets the balance established between the organism and the system marked by hypoplasia, or under the influence of some intercurrent infection or intoxication which brings into evidence its primal insufficiency. This latency is particularly striking when compared with the symptoms from acquired lesions of the same localization which are so often the cause of grave functional disorders almost from the start. This fundamental difference indicates the prognosis and the therapeutics. The lesions are not tuberculous in nature. The subjects are frequently free from the slightest tuberculous lesion and do not seem predisposed to them nor rendered immune against them. Early or late, however, the manifestations of this "para-tuberculous heredo-dystrophy," as Mosny calls it, become apparent, but the chlorosis, pure mitral stenosis, stenosis of the pulmonary artery or aorta, and diffuse arterial aplasia, alone or combined, have each their special features which allow them to be differentiated from acquired lesions.

51. **Indicanuria in Stomach Affections.**—Carles concludes from study of 22 subjects that indicanuria is not observed in hyperchlorhydria, but is almost always constant in case of deficient secretion of the gastric juice or hydrochloric acid, and also in case of fermentations in the stomach. The liver functions do not seem to have much to do with indicanuria, but it appears to be intimately connected with the functioning of the gastric mucosa. Indicanuria indicates not only the measure of gastro-intestinal fermentations but is also an index of the gastric secretions.

53. **Continuous Bronchopneumonia.**—Rosenthal's 3 cases were all due to the enterococcus of Thiercelin, and commenced with ordinary bronchopneumonia. The long duration, predominance of general phenomena, attenuation of the functional signs, slight hyperthermia, sometimes polycyclic, and the cachexia, simulating that of tuberculosis, are all included in the syndrome. No Koch bacilli could be discovered. The patients were pining in the hospitals when the fresh-air cure was instituted with prompt and rapid recovery in each case.

62 *Le traitement des tuberculeux dans les colonies familiales. H. Erni (Gersau, Switzerland).

61. **Influence of Malaria on Beri-Beri.**—In Urriola's experience at Panama he has examined the blood of 22 patients with beri-beri, and invariably found the malaria parasite. The beriberic symptoms, he mentions, always followed the onset of malarial symptoms. He thinks that there is more than a mere coincidence in this fact. Almost all the beri-beri deaths were due to heart complications, and loss of memory was frequent and so complete in one instance that the subject was unable to follow any occupation. The heart symptoms of the beriberi were dyspnea at the slightest effort, embryocardia and increasing asphyxia to fatal suffocation, but no true cardiac soufiles were noticed. Manson's "pendulum" sign has only relative value, as the memory suffers in beri-beri and the malaria induces a characteristic endocarditis and probably also a myocarditis with granulo-fatty degeneration. In most cases, therefore, it is impossible to establish a difference between beri-beri and malarial neuritis, and in fact, Urriola thinks there is no difference, and that the two are identical. Before incriminating the humidity or the food in the etiology of beri-beri we must first exclude or cure the malaria. He has been very successful in curing beri-beri by applying suspension, quinin, iron, and cold hydrotherapy. His patients were completely cured by 15 to 30 applications of suspension supplementing the other measures.

62. **Treatment of Consumptives in Family Colonies.**—Erni describes the homes offered to tuberculous subjects on the slope of the Righi. There are several villages at different altitudes where the families make a practice of taking tuberculous subjects into their homes. The fare is simple; little meat, but eggs and milk in abundance, five or six meals a day, and the host watches over his guests to see that no undue exercise is taken. In fact, long walks are impossible as the ascents are so steep. The price of these accommodations is not more than $4.20 a week, and the inmates thrive under the enforced repose and patriarchal conditions, as well as in pretentious sanatoria. Some families take only 2 or 3, others as many as 8, and during the last ten years nearly 2,000 tuberculous guests have been thus received in the canton of Schwyz. The village physicians have looked after them at reduced rates. Erni recommends this plan of mountain family colonies as having proved its usefulness at the minimum of expense. Nothing has been observed during the ten years that suggests that any of the hosts have become infected from their guests. The plan offers a means of gain to these mountain villages, which they are glad to exploit under the supervision of the local physician. The lack of comfort is no detriment.

63. **Treatment of Tuberculosis of the Male Sexual Organs.**—Büngner reports continued success with his method of treating tuberculosis of the male genitalia. It includes what he calls "high castration," that is, castration with evulsion of the vas deferens. Instead of dividing the vas at the ordinarily accessible point, he mobilizes and pulls steadily on it until it breaks high up. About four-fifths of the vas can usually be removed in this way, and his experience during nine years has demonstrated that the remaining portion soon heals. His method also includes direct injection into the vas deferens of a 10 per cent. glycerin solution of iodoform. He injects 3 or 4 gm. upward and 1 or 2 downward. Experiments on the cadaver show that the solution permeates the entire generative tract on this side, even distending the seminal vesicles. His experience also confirms von Bruns' that tuberculosis of the generative tract is almost invariably ascending, so that by this method of high castration all or nearly all the morbid parts are removed and the rest soon heals when freed from irritation from below. He has treated 18 patients by this high castration, which he recommends for tuberculosis restricted to the testicles and vas alone. He supplements it with the intracanalicular iodoform injections when there is reason to think the entire tract is invaded, including the seminal vesicles and prostate, or applies these injections alone. As a last resort, he ablates the tract the entire length of its course. The latter is very seldom necessary. All of his last series of 10 were cured, and all but 2 of the remainder. This is a total of 86.6 per cent. cured in contrast with Bruns' percentage of 46 per cent. cured by unilateral castration and 56 per cent. by bilateral, in 111 cases followed for three to thirty-four years. Simon has reported from Heidelberg 66.3 per cent. cured in 92 cases, and Kocher 26.3 per cent. in 45. Injurious after-effects that might be attributed to the castration were not found by Bruns in any of the 33 examined and by Simon only once in 34. Büngner details the particulars of his last series of 11 cases, and in the colored reproduction of the testicles, etc., and vas from a cured case he shows how the vas was diseased far above the point where it is usually severed. He has found that the epididymis is generally first involved and the vas next, the testicles being affected much less frequently than the latter. Only in the rarest cases were the prostate and vesicles also diseased. In 2 of his cases, high castration plus a single intracanalicular injection resulted in the complete healing of the lesions above, which were to have been removed later in a second intervention. One was a man of 39 and one a boy 4 or 5 years of age.

66. **Ligature Treatment of Hemorrhoids.**—Ehrich thinks that ligature is far superior to excision or cauterization in treatment of hemorrhoids, as far as the simplicity of the technic and of the after-treatment is concerned. At the same time it guarantees better against complications of various kinds, and is fully the equal of cauterization in respect to the ultimate outcome. He has thus treated 58 patients and 14 others plus excision of some of the nodules. In 16 cases he supplemented

the ligature by injection of one or two drops of a 90 per cent. solution of carbolic acid, protecting the sound parts with alcohol. Three cases were treated by these injections alone. All of his total of 98 patients were cured in ten to fourteen days; a few required a single injection of morphin on account of pain in the region. Catheterization was necessary in 11 cases. The nodules drop off in dry necrosis. Recurrence after ligature treatment occurred in only 4, and in 4 the benefit was merely partial, but 68 have been permanently cured. The only mishap in his experience was the death of one patient the seventh day with symptoms of embolism of the lungs, who had been treated by ligatures alone.

68. **Primary Cancer of the Extremities.**—Franze has had occasion to observe 21 cases of a malignant growth on an extremity. In 11 it developed at the site of some old injury, mechanical, thermic or chemical. In this group the glands are involved very late and the possibility of early removal of the neoplasm renders the prognosis good; 69.7 per cent. were cured and 30.29 per cent. succumbed. In another group were 5 cases of primary cancer on sound skin, the back of the hand in 3 and the thigh and heel in 1 each. None of these patients died. His third group includes those in whom the cancer developed from a congenital wart or maternal mole, 5 in all, and all fatal. The back of the hand was involved in 2, the sole in 1, the forearm in 1, and the left calf in the fifth. He has found 8 similar cases on record, all likewise fatal, and only 1 has been published in which there has been no recurrence since ablation. They usually occur in elderly persons and run their course in a year and a half. He thinks that the physician ought to impress on his patients the necessity of prophylactic removal of these congenital warts and moles, including the pigmented nevi, the latter on account of the liability of melanosarcoma. The mortality of the combined statistics shows 65.2 per cent. cured and 34.8 per cent. mortality or omitting the malignant third group, the mortality has been 30.3 per cent., with nearly 70 per cent. cured.

69. **Consequences of Nephrotomy.**—Langemak warns that his experience with rabbits indicates that any deep incision into the kidney induces an infarct, corresponding in size to the artery that is severed. Also that coagula may plug the entrance into the ureter, causing temporary insufficiency of the kidney. This latter danger should never be forgotten in operating on the kidney, and hemorrhage into the organ should be avoided and all blood in it should be carefully removed.

74. **Sarcoma of Spleen.**—The experience at Königsberg demonstrates that the spleen should be removed on suspicion of sarcoma, without waiting for definite and serious symptoms. In 7 cases operated on and published in the literature the results were favorable in 6, as also in a case personally observed. The latter patient was a woman of 38 from a malarial region, a multipara, who had noted at long intervals pains in the left half of the abdomen. The blood was apparently normal.

75. **Free Body in Abdomen.**—A supposed tumor on the rectum, protruding into the Douglas cul-de-sac, was extirpated and found to be a necrotic and calcified fibrolipoma that had been cast off from the omentum. It had lodged on and grown to the rectum. Similar lipomata were found scattered over the omentum at the autopsy, and evidences of carcinomatous degeneration were also discovered which explained the symptoms observed and credited to the bunch palpated in the Douglas sac.

76. **Malignant Struma.**—Ehrhardt remarks that malignant struma usually develops in a goiter, but not always. Ordinary goiter is movable as a rule, but the malignant struma does not move during the act of swallowing. This absence of movement was noted in 40 per cent. of the cases of malignant struma on record. He has collected 131 cases of carcinoma with glandular metastases in 49, and 107 cases of sarcoma with glandular involvement in 18. In operating general anesthesia should be avoided.

78. **Considerate After-Treatment of Septic Operations.**—Küttner hints that when a surgeon has been himself the subject of a septic operation he is better able to appreciate some of the details that add to the comfort of the patient. Among these is the use of drain tubes instead of gauze, as easier to change. If the temperature and pain do not increase, why not leave the dressings untouched for days? And if moist dressings are applied why not apply fresh ones outside and leave the one in contact with the wound undisturbed? The practice of cauterizing wounds with pure carbolic acid is particularly useful, as it reduces the secretions in the wound for days. A wet dressing soothes pain far better than a dry one. In replacing tampons in a crevice or narrow cavity, much pain is avoided by having the lips of the wound gently pulled apart by retractors. The wound surface should be touched as little as possible, and as soon as the acute inflammation is past, apply the salve dressings. If new incisions become necessary do not attempt local anesthesia, as it is liable to fail in the debility of extensive septic processes. Operate during the "ether drunk," that is during the first few whiffs of ether.

79. **Scopolamin-Morphin Anesthesia.**—This method of anesthesia was used in 105 cases at the Carlsruhe clinic. In the majority, Blos states, it proved "ideal." It failed in 29 cases, and in two-thirds of these ether had to be given to complete the operation. Hysteric and neurasthenic patients are liable to react with restlessness, palpitations and vomiting, even to small doses. The danger in this method of narcosis is from arrest of the circulation. There were respiratory disturbances in 9 of the 70 cases in which it was administered unmodified. In 4 of the 9 the disturbances were slight and spontaneously righted themselves at once; in 2 after massage had been applied to the heart and in one each after artificial respiration or wiping out the throat. A few vigorous pulsations of the heart—induced by the massage—had a particularly favorable action on the respiration. One patient died, the death explainable by advanced pulmonary lesions, nephritis and heart weakness. The narcosis is rarely so deep but what the subject can be roused by shaking and calling to him—a great point in its favor. He thinks that inhalation of oxygen might be useful in case of trouble. The mucous glands are paralyzed by this narcosis and consequently ether given afterward has none of the dangers as under other circumstances. His experience indicates that 10 dmg. scopolamin and 6 cg. morphin is the best dose to start with. After waiting an hour or an hour and a half, a second smaller dose may be given but can usually be dispensed with. Vomiting was noted once or twice in 12 of 99 cases. It was not accompanied by nausea. [The latest communication on the subject by Schneiderlin, the inventor of this method of narcosis, was reviewed very fully in THE JOURNAL of April 11, 1903, p. 1036.]

82. **Spontaneous Gangrene of the Extremities.**—Wartburg describes 3 cases of gangrene from embolism of the iliac or femoral artery, traceable to a valvular affection, and 1 due to an aneurism in the popliteal. He has also observed 5 cases in which the gangrene was due to thrombosis, evidently the result of a circumscribed endarteritis subsequent to some infectious disease. Pains in the limb had been noted as the first symptom. Amputation may cure in these cases as the prognosis is better than in the first group. The mortality in 32 cases of senile gangrene was 63.75 per cent. The gangrene is probably due to arteriosclerosis in senile as also in diabetic gangrene, of which he has observed 8 cases. The prognosis after amputation is more favorable in diabetic than in senile cases. All were cured in 6 treated by exarticulation of the knee, and 4 were cured in 7 after amputation of the thigh.

83. **Foreign Bodies in Air Passages.**—Monnier expatiates on the value of direct bronchoscopy and urges that we must not be deceived by the mildness of the symptoms noted after a foreign body has been drawn into the air passages.

84. **Intermittent Hydronephrosis.**—The details of 133 cases collected are tabulated, plus 8 unpublished ones.

86. **Extraction of Foreign Body from Bladder with a Magnet.**—An iron peg, 5 cm. long by 6 mm. wide, was inserted in the urethra by a young man and slipped into his bladder, where it could be seen by radioscopy. It was extracted by means of a Hirschberg portable magnet, the short tip used in ophthalmology being replaced by a long one, shaped something like

a catheter, considerably wider than the peg. A hair pin in a woman's bladder was also successfully removed with it.

89. **Urotropin in Prophylaxis of Typhoid Bacteriuria.**—The articles in this Festschrift in honor of Professor A. Pribram of Prague, all issue from his clinic. Fuchs states that urotropin administered in time to typhoid patients will effectually prevent bacteriuria later. He found bacilli in the urine in 26 out of 75 cases of typhoid fever, while in 40 treated with the urotropin, only one had bacteriuria, and in this latter case the drug had not been given as early as to the others. It must be commenced before the fever subsides, 2 gm. in an aqueous solution daily, and continued into convalescence to the latest date at which bacteriuria is liable to develop.

96. **Etiology of Acute Articular Rheumatism.**—Philipp believes that this disease is one apart from others, of entirely unknown etiology to date. No substance has yet been isolated from the blood or joint exudate which is pathogenic for any animal except the calf. Experiments with calves seemed to suggest a positive result and further tests with this animal are necessary. If the calves could be left with the mothers better results would probably be obtained than was possible under the circumstances in his experimental researches.

98. **Clinical Pictures in Ten Cases of Diabetes Insipidus.**—Besides the usual polyuria and polydipsia which in one case were superposed on a diabetes mellitus, nearly all the patients exhibited some affection of the central nervous system, especially genuine atrophy of the optic nerve. The peripheral nervous system was involved in a few, sciatica in some cases and exaggeration of the knee-jerk. The sexual functions were disturbed in nearly every instance. Evidences of arrested development were prominent in the younger subjects; in one case before the advent of the polyuria. In some instances there seemed to be a reversed proportion between the pulse and the polyuria. The heart beat and radial pulse were weak. In one case there was a hemorrhagic diathesis and in another incontinence of urine. All the patients were benefited by ergot and gradual deprivation of water, but a permanent cure was not obtained in any instance.

99. **Study of Diabetes.**—The practical conclusions of this comprehensive article state that in the dietetic treatment of diabetes the amount of fat to be allowed should be determined for each individual case by the intensity of the elimination of the acetone bodies. The tests showed a marked decrease in the elimination of the acetone bodies after administration of gluconic acid, a fact which, as Schwarz remarks, requires confirmation. The interposition of a day of fasting during the transition from a mixed to a diet free from carbohydrates, seems to reduce the acetone bodies at once and hastens the vanishing of the sugar. The tests also showed that the proportion of fats in the blood is above normal.

100. **Tuberculin Reaction.**—Zupnik does not think that this reaction is specific to the species but merely to the genus. The susceptibility of a tuberculous man is a hundred times greater than that of a tuberculous guinea-pig. He states that he has observed a case of tuberculosis of the kidney which, from both the clinical and pathologic points of view, seemed to be typical. The bacilli causing it, however, were not the Koch bacilli, but merely an acid-proof variety, apparently a smegma bacillus.

102. **Experimental Circular Suture of Arteries.**—The experiments were made on 7 animals, including 2 horses. In 3 the lumen of the artery remained entirely permeable, and in 1 partially. An obliterating thrombosis occurred in 2, and is liable whenever the vessel is below a certain size. About 15 mm. seemed to be the limit. The walls of the vessels are thicker in man than in dogs, and Amberg reports that he has successfully applied a circular suture in a clinical case, invaginating the femoral vein with the artery over a magnesium prothesis shaped something like a napkin ring. Stubenrauch has experimented with this prothesis on the femoral artery in dogs, but thrombosis followed in every instance.

103. **Myositis Ossificans.**—The treatment of this affection can be only operative, removing the periosteum for 1 cm. if the morbid process be adherent to the bone. Two cases on record indicate that early massage might ensure the resorption of small foci of ossification. In 2 cases personally observed, the process spread from little islands of ossification in the interstitial connecting tissue, leading to hyperplasia and ossification from the proliferating perimysium. The growth was rapid and was removed in twenty-one and twenty-four days. In the 61 cases of this affection that have been published, the quadriceps was involved in 26; the brachial in 21; the iliopsoas in 3; biceps in 3; adductor longus in 3 and the triceps, gastrocnemius, gluteus, masseter and diaphragm in one each. It usually occurs when the muscles are at their prime and a traumatic factor was evident in many if not all of the cases.

104. **Four Cases of Tumors in Psoas and Internal Iliac Muscles.**—The lesions all simulated a tumor in the kidney or pelvis. Symptoms had been noticed for six to fifteen months before the operation. One patient was a woman of 47, who died two months after the fibroma had been removed from the iliacus; another a man of 37 with fatal recurrence of the spindle-celled sarcoma in three months after the intervention. A fibrosarcoma was removed from the third patient, a woman of 31, the tumor located in the psoas, and followed by rapid fatal recurrence. The fourth patient was a man of 26, and he recovered without mishap after removal of a myxofibroma in the psoas.

105. **Radical Treatment of Tuberculosis of the Knee.**—Mosetig restricts radical operation to persons under 50, although König has reported 50 per cent. cured in 100 elderly subjects treated by resection. The general condition is also an important factor in the ultimate outcome. During the last ten years Mosetig has done synovial arthrectomy in 7 and resection in 114 cases of tuberculosis of the knee, and six or seven-tenths of the total number were cured. All severer cases should be operated on at once, as the lesion is constantly spreading and the danger of general infection increasing. He operates under chloroform, resecting the parts involved, especially the bursa suburalis, which is a favorite location for

the morbid process. A thin curving slice is sawed off the head of the tibia, perpendicular to its long axis. If circumscribed foci are discovered on the sawn surface each is incised singly into sound tissue. After the cavity left has been disinfected with formalin and dried, it is filled with the bone filling, which Mosetig has previously described (see THE JOURNAL, page 1545 of the last volume). As the new bone forms and grows into the filling, it comes in contact in time with every particle of the iodoform. The halves of the patella are united with catgut passing entirely around it, and the soft parts sutured on each side of the patella, leaving a strip of rubber tissue at the bottom of the wound. The skin is then sutured with silk and the leg placed in a wooden splint, lined with cotton, covered with gauze. The splint is bound to the leg with gauze and an immobilizing bandage applied outside to include the entire limb. The leg is raised a little the first day. He has never had temperature in any case. The bandage is left undisturbed for three or four weeks, during which the patients remain in bed. The outside bandage is then removed and the patient allowed to go about on crutches. The limb can be used the seventh or eighth week, but a flannel bandage should be kept on a while longer and warm baths taken frequently. The patient leaves the hospital in two months. There is no limp when the sole is raised 2 cm. After a few weeks of careful use of the limb it can be used without fear in the hardest work. The harmlessness of the procedure is shown by the rapidity with which the patients completely recuperated, while the iodoform filling ensures smooth, rapid and permanent cure of the local lesion.

106. **Laparotomy and Ventral Hernia.**—By following Lennander's technic, an extramedian incision to avoid injury of motor nerves—the cause of atrophy in the muscles—and by leaving the fibers of the rectus intact between the cicatrix in the anterior aponeurosis and the peritoneum, Hirsch affirms that there can be no danger of ventral hernia later. He has watched the ultimate results in 41 cases thus operated on and found that Lennander's claims are justified.

107. **Osteomyelitis in the Side of the Sacrum.**—Gross has observed 6 cases and collected 10 in the literature in which the osteomyelitis was located in the lateral portions of the sacrum. In 10 the disease proved fatal. The osteomyelitis may be mild or severe, and much depends on proper surgical intervention, as he explains in detail. When a secondary abscess forms in the psoas it may be reached by resection of the sacro-iliac symphysis.

108. **Traumatic Paralysis After Fractures of Base of Skull.**—In Krähenmann's own 2 cases and in 3 he has found in the literature, there was trouble in swallowing, from unilateral paralysis of the palate musculature, and also disturbances in voice and speech from unilateral paralysis of the recurrent laryngeal. In 4 there was unilateral paralysis of the sternocleido and trapezius muscles, and in 2 unilateral loss of taste, in one instance only over rear part of one side of tongue. The injury to the nerves was located by these symptoms in the foramen lacerum posterius which transmits the three nerves involved. The sternocleido and trapezius muscles became paralyzed, but as other muscles compensated, there are no motor disturbances. Two of the 5 cases entirely recovered except for slight trouble in swallowing, still requiring care.

116 *Blood Count in Appendicitis, etc. E. Stadler (Leipsic).—Zur diagn. Bedeutung der Leukocytenwerthe bei den von Blindarm und Wurmfortsatz ausgehenden entzündlichen Prozessen.

112. **Secondary Tuberculous Affections of Cauda Equina.**—Bartels reviews the clinical picture in 2 cases personally observed and one other. If the tuberculosis develops secondarily to a tuberculous affection in the sacroiliac symphysis and adjoining bones of the pelvis, the nervous symptoms from compression of the cauda equina usually locate the lesion without difficulty. He considers surgical intervention justified when the spinal vertebræ are not affected and the symptoms indicate compression by the upper portion of the sacrum. There is little to be gained from an operation if only the lower portion of the sacrum or the coccyx is involved.

113. **Probable Spontaneous Retrogression of a Tumor in Spinal Cord.**—Henschen's report of the recovery of a patient who exhibited symptoms of a tumor in the spinal cord which later apparently vanished, was reviewed in detail in THE JOURNAL when first published in the *Upsala Lakarefor. Forhandlinger*, vii, 8. The abstract will be found on page 1554 of vol. xxxix.

114. **Indications for Removal of Spleen.**—Jordan has become convinced that the spleen is an organ which can be easily spared; and that the removal of a movable spleen may be regarded as an almost entirely harmless intervention. The danger increases in proportion to the number and extent of the adhesions. The most favorable chances are when the affection is strictly localized to the spleen; if it is secondary to some constitutional affection, extirpation is dangerous. The statistics show that spleen affections are more frequent in women than in men. He has performed splenectomy six times with success and reviews 10 other cases he has found in the literature. He corroborates the existence of a chronic hyperplasia of the spleen which develops as a purely local lesion, affecting chiefly women between 20 and 30, and requiring years to develop, eight to fourteen years in the published cases. The spleen tumor is the only morbid process and the sole cause of the existing disturbances. The symptoms are those of crowding other organs or tissues. The spleen may grow to a weight of 2 to 6 pounds. The normal condition of the blood, liver and glands excludes a constitutional affection, and complete recovery follows the removal of the spleen, which is easily accomplished. Even the coexistence of cirrhosis of the liver is no contraindication in case of this primary, idiopathic hypertrophy of the spleen. Splenectomy has been done twice on account of primary tuberculosis of the organ, and in each instance a complete cure was effected. In case of a wandering spleen, if at all abnormal, ablation is indicated and also in case of doubt. The friability of the organ renders the results of splenopexy dubious, although theoretically indicated. Necrosis of the spleen with perisplenitic suppuration such as has been observed after trauma, and intrasplenic hematogenic abscesses indicate operation. The results have been remarkably favorable in such cases to date. The seven on record were all cured. Compensation soon develops after splenectomy, even in debilitated or pregnant subjects. Recovery was also complete in a case of primary malignant tumor of the spleen treated by splenectomy. In case of echinococcus and blood cysts, the organ should be removed unless bound down by adhesions. Extirpation should also be the rule in appropriate cases of malarial spleen hypertrophy.

116. **Leucocyte Count in Inflammatory Processes Originating in the Cecum and Appendix.**—Stadler has examined 70 cases and confirms the experience of others in regard to the value of the leucocyte count in differentiating simple fibrinous exudate from abscess formation. In the former there may be in the beginning a leucocytosis of 23,000, but it rapidly subsides. If the number of leucocytes remains continuously high or reaches or surpasses 25,000 later in the affection, an abscess may be assumed or retention of pus. In case of diffuse peritonitis the height of the figure is not so characteristic as its tendency to rise or fall.

123. **Influence of Fats on Hyperacidity.**—Walko has been studying the effect of olive oil on the stomach. He found that it not only retarded the secretion of hydrochloric acid, but also restricted within much narrower limits the proportion of free acid and total acidity in the further course of the digestive process. The results of a number of clinical tests are tabulated, which demonstrate that 50 c.c. is fully as effective as 200 in this respect. Another set of tables shows that the amount of fat-splitting ferment in the stomach is largest after ingestion of milk, smaller after meat and smallest after ingestion of carbohydrates. In another series of 8 clinical tests he found that the simultaneous ingestion of 50 c.c. of oil with other food does not disturb the proteolysis, and in case of hyperacidity, the digestion of albumin and of starch proceeds much more rapidly than without the oil. The favorable influence of oil and other easily-digested fats is felt not only in the stomach but in the small intestine and in the relief of constipation. On the basis of the result of these researches he has been applying olive oil extensively and systematically for the treatment of hyperacidity. He administers it in a tepid emulsion, through the stomach tube, increasing from 50 c.c. at first to 100 or 200. The patients sometimes preferred to drink the oil, and all gained from 4 to 10 pounds in four to six weeks. His experience includes 92 patients thus treated during the past two years. Some were cases of acute hyperacidity, others chronic, and all forms of secretion neuroses and acid hyperesthesia, chronic ulcer, chronic gastric catarrh and ulcer scars. He has also been much impressed with the value of bone marrow taken with the dinner. This contains 96 per cent. of fat and has a marked inhibiting action on the secretion of hydrochloric acid. He details experiments with atropin and sodium bicarbonate, which showed that the relief from either was only temporary, while the bicarbonate has a distinctly injurious action, more and more acid being secreted to neutralize the alkali. He found decided and permanent benefit from Carlsbad water or Carlsbad salts in case of hyperacidity in otherwise healthy persons, but it induced motor insufficiency in debilitated subjects. In case of ectasia with hyperacidity he always obtained excellent results from lavage of the stomach with a 1 or 2 per cent. saline solution, followed by pouring in of 100 or 200 c.c. of olive oil. He remarks that it is important to siphon out the last drops of the water introduced. He adds, in conclusion, that hyperacidity of the stomach is frequently benefited by a decided change in the diet, and that the subjective state of health is perhaps the best criterion, but the dietary should always include some easily-digested fats, such as milk fat, butter, bone marrow or an oil emulsion.

129. **Gummatous Affection of Female Urethra.**—Löwenbach has observed 28 cases of this comparatively rare affection. The lesions may resemble gummatous formations elsewhere, but are usually distinguished by a peculiar tendency to hyperplasia of the margins of the elephantiasic tumors and their cicatricial terminal products. They also display a marked tendency to recurrence at the same or adjacent points, and are rebellious to the usually effectual mercurial treatment. Persevering administration of iodid finally conquered the affection in a few instances. He illustrates some of the cases with colored plates.

132. **Arteriosclerosis in the Young.**—Sumnitzky was amazed to find lesions of unmistakable arteriosclerosis in 27.5 per cent. of 38 cadavers of individuals under 25, free from syphilitic infection. He suggests that the acute infectious diseases probably play a more important rôle in its production than heretofore recognized. In 18 of the cases there had been previous severe pneumonia, diphtheria, scarlet fever, measles, typhoid, smallpox or chronic tuberculosis. In one pronounced case of arteriosclerosis in a child of 2, there was a history of diphtheria, followed by measles and later fatal pneumonia. In 3 others there was hypertrophy of the heart, from scoliosis or a history of epilepsy.

134. **Blastomycosis in Man.**—Bernstein describes a case of infectious disease with irregular fever in a little girl, two and one-half years old, fatal in less than two months. The autopsy revealed numerous foci resembling miliary tubercles, but no tubercle bacilli were found in them. Blastomycetes were found in the tissues and also at one time in the blood during life, but vanished from the blood later.

135. **Idiopathic Edema.**—No heart nor kidney lesions could be discovered in the case of chronic, idiopathic generalized edema described by Staehelin, and even at the autopsy no signs of an infection or intoxication could be detected.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE PRAXIS OF URINARY ANALYSIS. A Guide to the Chemical Analysis of Urine. With Directions for Preparing Artificial Pathologic Urines for Practicing the Various Tests, and an Appendix on the Analysis of Stomach Contents. By Dr. Lassar-Cohn, Professor in the University of Koenigsberg. Authorized Translation from the Author's Enlarged and Revised Second Edition. By H. W. F. Lorenz, A.M., Ph.D. (Berlin), Late Instructor of Organic Chemistry in the University of Pennsylvania. First Thousand. Cloth. Pp. 58. Price, $1.00. New York: John Wiley & Sons. London: Chapman & Hall. 1903.

A REFERENCE HANDBOOK OF THE MEDICAL SCIENCES, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition, Completely Revised and Rewritten. Army Changes.

Movements of Officers of the Medical Department, U. S. A., under orders from the Adjutant-General's Office, Washington, D. C., for the week ending June 22, 1903:

Arthur, William H., major-surgeon, will repair to Washington, D. C., and report in person to the governor of the U. S. Soldiers' Home for duty as attending surgeon, to relieve Major Louis A. LaGarde, surgeon.

Bloombergh, Horace D., first lieut. and asst.-surgeon, now on leave of absence at Easton, Pa., will, on the expiration of said leave, proceed to San Francisco and report for transportation to the Philippine Islands, where he will report for assignment to duty.

Brechennin, Louis, major-surgeon, is relieved from further duty in the Division of the Philippines and will proceed to San Francisco, and report by telegraph to the adjutant-general of the Army for further orders.

Crosby, William D., major-surgeon, will proceed to San Francisco and report for transportation to the Philippine Islands, where he will report for assignment to duty.

Fisher, Henry C., captain and asst.-surgeon, is relieved from duty as attending surgeon and examiner of recruits at Baltimore, Md., and from further temporary duty at Fort McKinley, and will proceed to Camp George H. Thomas, Chickamauga Park, Ga., for duty, to relieve Major William D. Crosby, surgeon.

Lyster, Theodore C., first lieut. and asst.-surgeon, is relieved from duty at West Point, N. Y., and will proceed to New York City for temporary duty as attending surgeon and examiner of recruits, to relieve Major William H. Arthur, surgeon.

McCalum, Francis M., contract surgeon, now on leave, is relieved from further duty in the Department of the Lakes, and will proceed to Fort D. A. Russell for duty.

Price, Richard J., contract surgeon, is granted leave for three months on surgeon's certificate, to take effect about July 1.

Purviance, William E., captain and asst.-surgeon, will report to Major Louis A. LaGarde, surgeon, president of the examining board at the Army Medical Museum Building, Washington, D. C., for examination for promotion.

Pipes, Henry F., contract surgeon, now in Washington, D. C., will proceed to Governor's Island, N. Y., and report to the commanding general, Department of the East, for assignment to temporary duty.

Wells, George M., captain and asst.-surgeon, will report to Major Louis A. LaGarde, surgeon, president of the examining board, at the Army Medical Museum Building, Washington, D. C., for professional examination for promotion.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending July 4:

A. A. Surgeon J. T. Miller, detached from recruiting duty and ordered home to wait orders.

A. A. Surgeon R. B. Chapman, detached from recruiting duty and ordered home to wait orders.

Medical Inspector D. N. Bertolette, ordered to Washington, D. C., as member of the naval medical examining board.

Asst.-Surgeon J. A. Murphy, detached from the *Monadnock* and ordered to the *Celtic*.

Asst.-Surgeon R. K. McClanahan, detached from the *Oregon* and ordered to the *Villalobos*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended July 2, 1903:

Surgeon Preston H. Bailhache, leave of absence for seven days from July 1, 1903, under paragraph 189 of the Regulations.

Surgeon H. W. Sawtelle, granted leave of absence for two days from June 30.

Surgeon J. M. Gassaway, granted leave of absence for two days from June 28.

Surgeon G. W. Stoner, leave of absence for two days from June 29, 1903, under paragraph 189 of the Regulations.

Asst.-Surgeon M. J. White, to report to chairman of board of examiners, San Francisco, July 10, 1903, for examination to determine his fitness for promotion to the grade of passed assistant-surgeon.

Asst.-Surgeon L. D. Fricks, to report to chairman of board of examiners, Immigration Depot, New York, N. Y., July 6, 1903, for examination to determine his fitness for promotion to the grade of passed assistant-surgeon.

Asst.-Surgeon A. J. McLaughlin, relieved from duty at New York, N. Y., and directed to proceed to Washington, D. C., for duty in the Bureau.

A. A. Surgeon G. T. Simonson, granted leave of absence for one day.

A. A. Surgeon Jay Tuttle, granted leave of absence for thirty days from July 1.

Pharmacist S. W. Richardson, relieved from duty at St. Louis, Mo., and directed to proceed to Portland, Me., and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist M. Walerius.

Pharmacist M. Walerius, on being relieved by Pharmacist S. W. Richardson, to proceed to St. Louis, Mo., and report to medical officer in command for duty and assignment to quarters.

BOARDS CONVENED.

Board convened to meet at Washington, D. C., July 3, 1903, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board: Assistant Surgeon-General L. L. Williams, chairman; Assistant Surgeon-General W. J. Pettus, recorder.

Board convened to meet at the Immigration Depot, New York, N. Y., July 6, 1903, for the examination of Asst.-Surgeon L. D. Fricks to determine his fitness for promotion to the grade of passed assistant-surgeon. Detail for the board: Surgeon G. W. Stoner, chairman; Surgeon C. T. Peckham; P. A. Surgeon T. Clark, recorder.

Board convened to meet at San Francisco, Cal., July 10, 1903, for the examination of Asst.-Surgeon M. J. White to determine his fitness for promotion to the grade of passed assistant-surgeon. Detail for the board: P. A. Surgeon W. G. Stimpson, chairman; P. A. Surgeon R. Blue; P. A. Surgeon H. S. Cumming, recorder.

DISMISSAL.

Asst.-Surgeon F. J. Thornbury dismissed, by direction of the President, from the Public Health and Marine-Hospital Service for conduct unbecoming a gentleman and an officer, insubordination, etc., to take effect on receipt of letter of dismissal (effective July 1, 1903).

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended July 3, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, June 20-27, 5 cases.
California: San Francisco, June 14-21, 2 cases.
Illinois: Belleville, June 22-29, 5 cases.
Indiana: Indianapolis, June 20-27, 1 case.
Louisiana: New Orleans, June 20-27, 4 cases, 1 death.
Massachusetts: Fall River, June 20-27, 3 cases; Taunton, June 20-27, 1 case.
Michigan: Detroit, June 20-27, 7 cases; Flint, June 20-27, 1 case; Grand Rapids, June 20-27, 3 cases; Port Huron, June 20-27, 10 cases.
New Hampshire: Manchester, June 20-27, 2 cases.
New Jersey: Bordentown, June 6-27, 24 cases, 5 deaths; Trenton, June 20-27, 1 case.
Ohio: Cincinnati, June 19-26, 3 cases, 2 deaths; Cleveland, June 20-27, 1 case; Toledo, June 13-20, 2 cases.
Pennsylvania: Altoona, June 20-27, 1 case; Johnstown, June 20-27, 1 case; Philadelphia, June 20-27, 26 cases, 4 deaths.
South Carolina: Charleston, June 20-27, 2 cases.
Wisconsin: Milwaukee, June 20-27, 2 cases.

SMALLPOX—INSULAR.

Philippines: Manila, May 2-9, 9 cases.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, June 6-13, 4 cases.
Belgium: Antwerp, June 6-13, 4 cases, 1 death; Brussels, June 6-13, 8 deaths.
Brazil: Rio de Janeiro, May 24-31, 1 death.
China: Hongkong, May 2-16, 12 cases, 1 death; Shanghai, May 9-16, 2 deaths.
Colombia: Bocas del Toro, June 9-16, 2 deaths.
Great Britain: Bristol, June 6-13, 1 case; Cardiff, May 2, 28 cases; Dublin, June 6-13, 15 cases, 1 death; Dundee, June 6-13, 2 cases; Leeds, June 13-20, 12 cases; Manchester, June 6-13, 9 cases, 1 death; Newcastle-on-Tyne, June 6-13, 1 case; Sheffield, May 30-June 6, 9 cases; Sunderland, June 6-13, 1 death.
India: Bombay, May 25-June 2, 44 deaths; Calcutta, May 23-30, 1 death; Karachi, May 23-30, 3 cases; Madras, May 23-29, 1 case.
Japan: Kobe, May 23-June 6, 5 cases.
Mexico: City of Mexico, June 7-14, 18 cases, 12 deaths.
Russia: Moscow, May 30-June 6, 2 cases, 2 deaths; St. Petersburg, May 30-June 13, 41 cases, 10 deaths; Warsaw, May 16-24, 2 deaths.
Switzerland: Zurich, June 6-13, 1 case.

YELLOW FEVER.

Colombia: Panama, June 15-22, 3 cases, 1 death.
Costa Rica: Limon, June 11-18, 2 cases.
Ecuador: Guayaquil, May 2-23, 6 deaths.
Mexico: Merida, June 1-20, 5 deaths.

CHOLERA—INSULAR.

Philippines: Manila, May 2-9, 44 cases, 38 deaths; Provinces, May 2-9, 343 cases, 242 deaths.

CHOLERA—FOREIGN.

India: Calcutta, May 23-30, 52 deaths.
Straits Settlements: Singapore, May 2-9, 72 deaths.

PLAGUE—INSULAR.

Philippines: Manila, May 2-9, 6 cases, 2 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, May 24-31, 1 death.
China: Amoy, May 16, present; Canton, May 16, present; Hongkong, May 2-16, 215 cases, 184 deaths.
Egypt: May 23-30, 4 cases, 4 deaths.
Germany: Berlin, June 5-18, 2 cases, 1 death, contracted in laboratory work.
India: Bombay, May 25-June 2, 186 deaths; Calcutta, May 23-30, 52 deaths; Karachi, May 24-31, 105 cases, 100 deaths; Mauritius, May 21-28, 1 death.

CLOSURE OF WOUNDS.*

MILES F. PORTER, M.D.

Professor of Surgery and Clinical Surgery, Fort Wayne College of Medicine.

FORT WAYNE, IND.

The methods of closing wounds now in vogue are not the best. This opinion is based on personal experience, observation of the work of others, inquiry and reading, and is the excuse I have for the presentation of this paper. I do not claim either priority or originality in the methods of wound closure advocated in this paper. My object in writing it is chiefly to urge a general adoption of the improved methods, and incidentally to show the desirability of a wider application of them than is made perhaps even by those who already use them.

For a considerable time I thought the method of closing wounds by tier sutures of absorbable material with a subcuticular suture for coapting the skin was the acme of perfection. Now, with rather rare exceptions, I never use a stitch in either the skin or subcutaneous tissue, but use adhesive plaster instead. The plaster is applied in strips about one-fourth of an inch in width, after the skin has been thoroughly dried. No more strips are used than are necessary to maintain perfect coaptation. If desired, they may be left on for two weeks. Some cases, as for instance operations for mammary carcinoma, will require either two or three tension sutures in connection with the adhesive strips, or instead the wound may be closed throughout with subcuticular stitches of catgut. Again, in rare cases a few stitches may be needed to obliterate dead spaces in very fat subjects. In these cases, however, it is usually possible to obliterate the dead spaces by placing strips of adhesive plaster over rolls of gauze placed parallel to the wound. I regard the use of adhesive strips in the closure of wounds as a long step in advance of the buried absorbable suture, which in its turn was a long step in advance of the older methods.

To-day, with the combined use of buried absorbable sutures and adhesive strips, results may be obtained which are far superior to those following the use of through-and-through sutures. Save in cases where much tension is necessary to maintain coaptation in the presence of infection, a suture through the skin is unnecessary, and will soon come to be considered as an evidence of want of skill or care on the part of he who places it.

Tension alone of the skin or subcutaneous tissues is not a sufficient excuse for placing a suture through the skin in a case where the avoidance of a scar is particularly desirable.

Superficial abscesses are less frequent with buried than with through-and-through stitches; they are least frequent when adhesive plaster is used and all stitches are avoided. There are three reasons why this is true: 1. There is better drainage when no stitches are placed. 2. The coaptation is more perfect. 3. Trauma is avoided. It may seem paradoxical to say that the drainage is better with the method which gives the most perfect coaptation. Nevertheless this is true. The blood which collects beneath the skin easily presses apart the elastic skin edges between the plaster strips and is immediately taken up by the gauze, and as soon as the oozing stops the skin again falls into apposition. I frequently remarked that the dressing over wounds closed with adhesive strips, other things being equal, was much more blood-stained than the dressings over wounds closed by suture. Perfect coaptation is, then, not incompatible with drainage. Indeed, the principal objection to the subcuticular stitch is that by its use the wound is closed too tightly. When suppuration does occur in wounds coapted by adhesive plaster it is of much shorter duration and less extensive than when stitches are used. By the use of adhesive plaster the scar is reduced to the minimum.

Another advantage of the adhesive plaster is that its use takes so much less time than does the placing of sutures by any method. The objection may be urged that there is danger of the plaster not being aseptic. There need be no fear on this score, however, as the plaster may be kept ready for use in an air-tight receptacle in the presence of formalin, which will thoroughly asepticize it without in the least diminishing its adhesive properties. I have used many of the rubber plasters in the market, and save that some adhere a little more strongly and promptly than others, I have found no difference in them. Plasters with much resin in them may irritate the skin.[1]

In operations about the face the avoidance of scars is particularly desirable. How common is it, for instance, to see the face of a patient who has been operated on for hare-lip terribly disfigured by scars caused by the stitches or pins used for purposes of coaptation. The cases of hare-lip requiring the placing of a stitch which shows are exceedingly rare. Subcuticular sutures with adhesive plaster is all that is required, and the results obtained will be found to be infinitely more satisfactory. Stitch-abscesses are a menace to life in a very slight degree only, but in however so little they increase the

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

1. Folding both ends of each strip of plaster so as to produce a hem, as it were, free from adhesion, will materially facilitate the removal of the strips. I am indebted to Dr. H. A. Duemling of Fort Wayne for this suggestion.

danger of operation this were a sufficient reason for doing all in our power to avoid them. In many cases the strongest reason for preventing suppuration of this kind is because it decreases the strength of the wound. For a through-and-through skin stitch, or a subcuticular stitch to be the cause of suppuration extending to the deeper structures is not an extremely rare thing. Generally speaking, animal sutures, with our present knowledge of preparing them, are not, as a rule, to be used in the presence of infection. This necessitates the use of non-absorbable sutures which can be removed when they have fulfilled their purpose. Such a necessity sometimes arises in operations for hernia. It can be met by placing the sutures mattress-fashion, and bringing the ends out through the skin and fastening them there by using perforated shot and buttons.

This method reduces the number of skin punctures to a minimum, and does away with the dangers incident to the constriction produced by tying the sutures in the ordinary way. Another plan which has been found to work well is the use of a running stitch of non-absorbable material, each end of the thread being fastened by the shot and button. The objections to this later form of suture are two: 1. Its removal is painful. 2. If suppuration does occur it will be more extensive, other things being equal, than with an interrupted suture. When either of these methods are used for the deep structures the superficial ones are coapted by the adhesive plaster. Still another plan which I have found to work well where for any reason non-absorbable material was deemed necessary for the deeper tissues is to place the stitches as though the usual figure-of-eight stitch were to be used, but instead of completing the figure by tying, and thus coapt the skin, each end of the thread is fastened by the shot and button at a short distance from the margin of the wound. The skin is then brought together with adhesive strips. No matter how fat the subject, the proper placing of this stitch will not only result in effectually coapting the deep structures, but will also prevent the formation of a dead space between the deep structures and the skin, and with a minimum of constriction and trauma, both of which are particularly to be avoided in fatty tissue.

Save in intestinal work, I believe that non-absorbable material should not be used for suture with a view of allowing it to remain permanently. Personally, I have not for five years seen a case in which I thought such use necessary or advisable. Within this time I have operated on several large scrotal and umbilical hernias. I said in an earlier part of this paper that animal sutures were usually contraindicated by the presence of infection. This, I think, is correct, and yet I have used them under these circumstances, with the most gratifying results. In a case in which a large part of the half of the lower jaw was resected together with a portion of the cheek for an infected carcinoma I closed the wound throughout, except for one silkworm-gut stitch next to the drainage tube, with subcuticular catgut stitches and adhesive plaster, with the result that the scar was reduced to a line in width, save at the exit of the tube and the location of the through-and-through stitch. The necessity for drainage for other than infectious fluids is not a bar to the use of animal sutures.

In the presence of infection necessitating drainage there is especial reason for avoiding sutures particularly to coapt the skin or subcutaneous tissue. In such cases only such sutures should be used as are absolutely necessary to coapt the deeper structures, and the superficial ones should be coapted by the use of adhesive strips. Even these deeper sutures can be avoided in many cases wherein they are now, by the majority of operators, deemed necessary. To illustrate, an amputation of the arm seldom, if ever, requires a suture, and, as indicated above, they are especially to be avoided in such operations done through infected tissues. Court plaster, collodion and cotton and collodion alone are inferior to aseptic adhesive plaster. The reasons for this opinion, it seems to me, are too patent to require their being given.

CONCLUSIONS.

In conclusion, I desire to emphasize the following points:

1. The use of sutures should be avoided save where necessity demands their use. Many wounds, in which sutures are now commonly used, may be coapted more perfectly, more speedily and more safely without the use of sutures.

2. Tension and moisture are the only conditions making sutures necessary.

3. When sutures are necessary buried absorbable sutures should be used in all cases where there is no infection.

4. The necessity for drainage does not contraindicate the use of adhesive plaster for purposes of coaptation.

5. It is doubtful if the use of non-absorbable suture material should ever be used with a view to its remaining permanently.

6. Non-absorbable sutures are not necessary nor advisable save in intestinal work and in the presence of sepsis.

7. In those cases in which non-absorbable sutures are necessary that method of applying them should be chosen which will subject the tissues to the least possible trauma, produce the fewest possible avenues for infection through the skin, and permit of their being removed when they have fulfilled their mission.

207 W. Wayne Street.

DISCUSSION.

Dr. John E. Summers, Jr., Omaha—When I commenced the practice of medicine more than twenty years ago I used plaster in the open treatment of wounds. With our modern methods of the treatment of wounds we discarded plaster, and we discarded a very useful material, but probably it was a good thing, because it taught us to be more cleanly; but as plaster is made to-day there is no doubt that it can be used, and there is no question that thoroughly clean work can be done with it. The technic which Dr. Porter brings to our attention seems to me to be ideal. For the repair of wounds we have two or three things to consider: we must have accurate hemostasis; we must have exact coaptation of the edges, and from the bottom to the top the wound must be held together without tension. If this can be accomplished, we have done all that is necessary, and the very best things that can be done.

This can be accomplished in the superficial wounds always, but in the deep wounds I doubt whether it can be done, and as the Doctor has suggested, it may sometimes be advisable to use some kind of a stitch as an aid to the result desired. I would hesitate very much to rely entirely on plaster strips for the coaptation of abdminal wounds, except in selected cases where a normal convalescence was assured. Now in an abdominal operation of any seriousness there is a certain amount of shock, with moist skin, and after the wound has been dressed the adhesive plaster may loosen and not keep the edges together. For this reason I hold that it is unwise to use plaster in wounds of that kind. However, when we do use adhesive plaster, I think you should have a pretty definite idea of how it should be applied, and judging from the Doctor's drawing, he does apply it as I think it should be. Both ends of the plaster strips should be applied at reasonably fixed points.

Below they should go over the crest of the ilium, and they should cross over the inner border of the latissimus dorsi muscle. Then you have two points as nearly fixed as they can be gotten. If it is applied in this manner, then you can be sure if distension occurs that the plaster will hold.

DR. HERMAN E. PEARSE, Kansas City, Mo.—The tendency of us all is to do too much suturing about wounds, too little of which is really effective. We must recognize the fact that one of the most prominent steps in surgery was taken when suture material was perfected. It seems to me that the plan that the Doctor advises of the surface approximation of wounds, and if necessary the absorbable suture below the surface is a most excellent one. It has never seemed to me safe surgery to depend entirely for the closure of abdominal wounds on absorbable sutures. It may be that one or two unfortunate instances have made me more cautious in this regard. I remember particularly one old lady, quite advanced in years, where healing was particularly slow, in which the absorbable suture was used, and through some defect in the suturing or suture material the wound gave away on the fourth day, and I was chagrined to see three or four coils of intestines roll out. These were returned, and a through-and-through suture applied, and the patient made an uneventful recovery without hernia, and yet I suspect that many a case has this accident beneath the skin. If the damage was done in the first few days, it might never be suspected by the surgeon, and there would perhaps be a sufficient union for the surface to heal, and leave the inner layers of the abdominal wall separated. It seems to me that this method is better than suturing for wounds on the extremities and about the face. I think that the through-and-through suture of silkworm-gut should be used in abdominal surgery in addition to the superficial suture. At least one should use a few such "splinting" silkworm-gut sutures in connection with the adhesive strapping and the absorbable sutures.

DR. ANDREW W. MORTON, San Francisco.—I have been very much interested for a considerable number of years in the use of adhesive plaster for the closure of wounds, and I do not think we should let this speaker go on record without a challenge. In the first place the Doctor speaks of closing wounds in the abdominal cavity by means of adhesive plaster, without using any suture to close the fascia. We all know very well from our experience in abdominal surgery that the principal thing that gives strength to the abdominal wall is the fascia, and if it is not brought together by means of stitches, how can it be brought together? The adhesive plaster simply pulls the outer structures together, and the fascia, which gives strength to the abdominal wall simply disappears by retraction. You can simply make coaptation of the skin by means of the adhesive plaster. but not of the deep structures, and if there is one thing that we are taught in surgery, it is not to leave any dead spaces. You take any deep wound and it is practically impossible to prevent dead spaces occurring by means of the adhesive plaster. I speak on this subject because I find that there is one thing that we are prone to do with any new subject, and that is to go to the extreme. Now, in closing superficial wounds, we have long since learned that it is an admirable method, because, in that condition we generally have a very low vitality of the structures, and on account of the amount of pressure which is necessarily brought to bear in closing these wounds by a stitch, which produces tissue necrosis—always an unfavorable condition. Another thing in regard to the use of the stitch, and the principal reason why the stitch is so often objectionable is on account of infection. In my opinion there are only two reasons for getting infection: First, not being aseptic, and second, surgeons all over this country in tying a stitch, put too much strength on it, and as a result they get tissue necrosis, which invites infection. To-day there is not the objection to the use of buried catgut sutures that there was a few years ago. I can see no objection to the use of the adhesive material, if you use the absorbable catgut suture, or chromatized catgut, to close the deep wounds. There is only one form of adhesive plaster with which I have had a large experience, and that is the form prepared by oxid of zinc. The first I used was the other, and I found that eight or ten days after the operation there was great danger of excoriation of the skin, which is naturally painful and dangerous. This excellent paper brings our attention to one of the prominent things in surgery, but I believe that the Doctor is using it in cases where it is hardly justifiable.

DR. WILLIAM M. PERKINS, New Orleans—In many wounds perfect union may be prevented by maceration of the tissues or by slight hemorrhages either subcutaneous or appearing between the stitches. Sutures have a distinct hemostatic function which can not be satisfactorily performed by adhesive strips. The perspiration, when confined by an impermeable covering, may cause sufficient maceration to greatly favor superficial infection. Germs like heat and moisture. Asepsis is a relative term; practically no wounds are germ-free, but we aim to limit the numbers of pathogenic micro-organisms and to secure conditions unfavorable to their development. It is often advantageous, especially in warm climates, to afford free ventilation to the gases under a dressing. Adhesive plaster prevents this to some extent. The whole theory of the use of *absorbent* gauze and cotton is based on the necessity for having a dressing which will keep wounds free from moisture and allow for the circulation of gases. Adhesive plaster strips are an excellent means of closing many wounds, but are by no means universally applicable.

DR. MILES F. PORTER, Fort Wayne, Ind.—I can not consider it possible that my paper was misunderstood by very many, as it seems to have been by this gentleman. I stated that you could not use adhesive plaster where there is tension, and there is tension where you coapt a hernia wound. I have used the adhesive plaster for the purpose of coapting wounds that could be coapted by it, and not for the purpose of deceiving myself. I stated that wherever there is tension, it must not be used. The method I ordinarily employ in abdominal wounds is to use the tier sutures of absorbable catgut, sterilized, for the deep structures and plaster for the skin. I have never had occasion to be sorry for it, although in some cases I have had occasion to be sorry that I made the operation, as in such cases as those related by Dr. Summers. Vomiting with opening of the wound, however, will occur when non-absorbable sutures are used as often as when absorbable sutures are used. I agree with Dr. Summers that it is advisable sometimes to employ stitches of nonabsorbable material. In regard to the moisture that you have when you coapt the skin with adhesive plaster, I do not know how it would be in this climate, but I have closed over one hundred wounds in this manner without trouble from this source. Beneath the plaster, of course, there is a small amount of moisture which comes from the follicles.

When you come to remove these little strips of plaster, oftentimes it is hard to pick up the end, but if you will just take the strip and turn in a quarter of an inch on each end before applying it to the wound, then you can take hold of each end very easily. Now regarding the treatment of abdominal wounds. I use short strips of adhesive plaster, three inches in length and one quarter inch wide, to coapt the skin, and over the dressing I place long, wide strips of adhesive plaster that reach three-quarters of the way around the body. My strips of adhesive plaster are put on solely with a view of keeping the skin and subcutaneous fat coapted, and you can not keep anything else coapted in that manner. If the man who has made many operations on the face using through-and-through sutures will try the subcuticular stitch with adhesive plaster, I warrant you he will never go back to the old method.

For Prickly Heat.—*Clinical Medicine* suggests, since prickly heat is caused by the irritation from perspiration which can not readily evaporate, that it will be found better to resort to soap and water, used frequently, and to avoid alcoholic and alkaline washes. Once a day, perhaps, the irritated parts should be gently bathed, then dried thoroughly, and afterward anointed with cocoanut oil; which is absorbed readily, and should be applied with the hand. It is not greasy, and will not soil the clothing unless an excessive quantity is used.

A CASE OF ACUTE, NON-TRAUMATIC, MULTIPLE OSTEO-MYELITIS,

PRODUCED BY THE STREPTOCOCCUS, OCCURRING IN A MALE ADULT.*

JOHN T. BOTTOMLEY, M.D.
BOSTON.

NARRATION OF CASE.

A. H. C., 43 years old, a theatrical manager, was born in France, lived most of his life in England, and had been five years in this country. His family history was negative. His previous history up to 1892 was not noteworthy. Though he had led an irregular life, with much excitement, travel and exposure, he had always been strong and robust. Venereal infection was denied; a moderate use of alcohol admitted. About 20 years ago he broke his left tibia at the junction of the lower and middle thirds, but it had given him no bother since.

Ten years ago he had an attack of "left-sided pleurisy" which lasted about six weeks. Though he soon recovered his normal weight and strength, he has since then had more or less pain in his left chest, a harassing cough, an almost constant bloody expectoration and the lower lobe of his left lung has been flat to percussion. These symptoms have always been exaggerated after prolonged physical exertion or mental worry. Occasionally, but only for a period of a few weeks at most, he would be free from them. Such a period occurred last spring, but the symptoms, returning in June, continued till his death. Several specialists, both here and abroad, had examined him, but a definite diagnosis had never been made. The uniformly bloody, prune-juice expectoration had been carefully examined again and again for tubercle bacilli, streptothrix, actinomyces and for neoplastic elements, but always with negative results. He had undergone, as a diagnostic measure, most thorough anti-syphilitic treatment without relief or change in his condition. His symptoms, subjective and objective, continued the same year after year. Repeated punctures at different times showed only a thickened pleura. No fluid, purulent or otherwise, was ever obtained, nor was a cavity in his lung ever demonstrated. A distinguished New York specialist who saw him a number of years ago had an opportunity of re-examining him last fall and found the physical signs unchanged, which rendered very improbable the diagnosis of a slow-growing malignant tumor of the lung which had once been advanced.

Aug. 1, 1902, while making a railroad journey, very sudden and severe pain began both in his left arm just below the shoulder and in his left leg about the middle. Though he had considerable fever (103), the severe pain was his only subjective symptom for several days; then he had a chill, a diarrhea started in and he began to feel "sick all over." A physician was called who reports that at that time (six days after the acute onset) there was "a swelling with deep pain on pressure over the inner surface of his left upper arm, at the junction of the middle and upper thirds. There was also deep induration over the outer aspect of the middle third of the left leg. Both arm and leg were swollen and the swellings were so tender that a thorough examination was impossible. There was no glandular involvements. The urine was negative; there was no temperature." Anti-rheumatics internally with local cooling lotions seemed to afford some relief for a day or two, but the pain then became more intense and the patient started a run of fever which varied between 100 and 102, but followed no definite type. Sweating now began, slight at first, but gradually increasing till it became a feature of his illness. A white count, made about the sixteenth day, showed a leucocytosis of 17,000. The patient became more and more ill; the temperature assumed a higher level and fluctuation finally appeared in the swellings on the arm and leg. A surgeon who saw the case in consultation at this stage opened the abscesses under local anesthesia, the patient's critical condition contraindicating a general anesthetic. The humerus and fibula were found to be partially denuded of periosteum, but "no connection with the bone marrow could be established." During the following month several operations were done on the left arm and leg to secure proper drainage. The symptoms, however, continued and the patient's condition grew gradually worse. His temperature varied from 101 to 103, while his pulse was about 125. A month after the onset of the disease his right forearm and right leg began to swell and to become tender and painful. An abscess over the upper part of the ulna was opened and drained; bare bone was once more found. The leg was not opened. The pus from all the abscesses showed the streptococcus in pure culture and the same organism was found in the expectoration. About the sixth week of his illness the state of the left arm became so bad that amputation was advised, but it was not done, partly because of the patient's unwillingness and partly because of his condition, which by this time had become so critical that even simple incision of an abscess under local anesthesia threw him into marked shock. For the latter reason a sequestrum which had formed in the left humerus was not removed. Numerous punctures into the flat area of the chest were made, but no pus was found. Yet a specialist in chest diseases who saw the patient in the sixth week of his illness diagnosed the chest condition as a pulmonary abscess.

Oct. 17, 1902, in the eleventh week of his illness, the patient came under my personal observation. He was emaciated and evidently septic. His temperature was running about 101.5, his pulse about 120. His respirations were only slightly accelerated. His chief subjective symptoms were his cough, severe pain in the left arm and right leg and moderate pain in his left leg and right forearm. His urine showed a slight trace of albumin, but was not particularly abnormal. He had an intermittent diarrhea which annoyed and weakened him greatly.

The whole left upper arm was swollen, thickened and edematous. On all its aspects were the wounds of his previous operations, some partially healed, some wholly open. From all came a free, foul-smelling, thick, purulent discharge; through all the examining finger could feel bare, roughened bone. The shoulder joint was involved in the process. The left forearm and hand were also swollen, but only as a result of the impeded return circulation.

On the external aspect of the left leg in its upper third was a partially healed wound about four inches in length. A sinus at its center led down to the fibula denuded of its periosteum over a considerable area. The discharge was not profuse. The upper half of the leg was only moderately swollen.

There was some general swelling of the whole right leg, but it was more noticeable over the lower half, especially just above the ankle joint, where there was marked edema and the tenderness was exquisite. The skin over this area was not reddened.

The right forearm was swollen from elbow to wrist, mostly posteriorly and on the ulnar side. Over the upper posterior surface of the ulna was a wound two inches long which, like the others, led down to bare bone and gave exit to a profuse discharge of thick pus. The elbow joint was apparently uninvolved, but was fixed at an angle of 45 as a result of its being held in that position for some weeks.

The rest of the story can be briefly told. At the first visit simple incisions were made in the right leg to relieve the tension and let out the pus. The previous incisions on the other members were lengthened to provide more effectual drainage. These procedures afforded so little relief that, after consultation with Dr. John C. Munro, radical measures were decided on, notwithstanding the critical condition of the patient. In two operations, one following ten days after the other, under general anesthesia, a very foul sequestrum six inches long was removed from the left humerus (the well-marked involucrum adding much to the difficulty of the operation), one

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

about four inches long from the left fibula and another about two inches long from the right ulna; the right leg was freely opened and large areas of bare bone found on both tibia and fibula; the tibia was trephined and, pus having been found in the medullary cavity, a gutter was made with a chisel down the whole front of the cortex. The medullary cavity of the right fibula was opened with rongeur forceps and drained. It was not so extensively involved as the tibia. The right ulna was treated likewise and free drainage provided.

Necrosis of bone was very extensive in the left humerus and right tibia. There was a large quantity of foul, thick pus in the soft parts of the lower right leg. The periosteum was but little thickened over the upper half of the tibia, but was retracted from a large portion of the cortex of the lower half.

These operations brought the temperature down to normal for the first time in the course of the disease and there it remained till the end, save when backing up of the pus on two occasions caused a temporary rise to 101. The pulse also fell to the neighborhood of 100 and for two weeks following the operations the patient was very comfortable and spent part of each day in a wheelchair. But, unfortunately, recurrent attacks of diarrhea, the several operations necessary to maintain proper drainage, with possible advancing amyloid disease of his internal organs, so weakened him that he died early in January, 1903, on the one hundred and fifty-fifth day of his illness. Without doubt he had septicemia. An autopsy could not be obtained.

His fever was at its highest during the third and fourth weeks, touching 104.8 on the twenty-ninth day. It touched normal for the first time on the ninety-seventh day. The average temperature was about 101.5; the average pulse about 115; the highest rate reached was 140, coincident with the highest point of temperature. Except for a period of two weeks following the free opening of the bones, the patient was very restless and nervous, particularly at night. On and off a severe diarrhea gave him much trouble and was most difficult to control. He took very large quantities of nourishment throughout his whole illness and had very little gastric disturbance. Profuse sweats were common; chills were absent. During the course of his illness he developed a marked pilosis—a condition not uncommon in these cases. His cough was very troublesome and the expectoration always blood-stained, sometimes with dark, but more often with bright blood.

The immediate cause of his death was cardiac failure, of which he had several attacks during the last two weeks of his illness.

COMMENTS ON THE CASE.

With regard to the diagnosis in the case there is but little to say. The long-standing affection of his lung, whatever may have been its nature, afforded to the streptococcus a focus of development in the body, a point of entrance to the circulation and a consequent opportunity to produce the unusual condition already described.

After the paper of Lexer[1] and that of Nichols, presented at the present meeting, there is at present nothing to be added to the bacteriology and pathology of osteo-myelitis. This clinical contribution to the subject has reason for its being in these three factors: (*a*) the case showed multiple foci; (*b*) it occurred in an adult 43 years old, and (*c*) the infecting organism was the streptococcus.

Acute multiple osteo-myelitis, while not a very rare disease, is still by no means common. Funke[2] reported to the Surgical Congress in 1895 644 cases of osteo-myelitis; of these only 37 were examples of the multiple type. Neumark[3] reports 30 cases, five of which were multiple; Volkmann and Roser[4] consider the multiple form rare, and Wenzel reports a single case in a girl of 13. Haaga[5] says that one-fifth of all the cases are multiple. But, apart from the question of the rarity of this form of the disease itself, the fact that the present case occurred in an adult far removes it from the ordinary run of osteo-myelitis cases. Only 56 of Funke's 644 cases were found in patients over 25 years old. Of the 37 cases with multiple foci, all—without exception—occurred in children. In fact, he says that the multiple form occurs only in children. Four cases mentioned by Volkmann[6] were all in patients under 14 years old.

In a fairly thorough search of literature I can find but one similar case of acute multiple osteo-myelitis occurring in an adult. H. F. Devel, in the proceedings of the Warsaw Society in December, 1885, reports the case of a soldier, 24 years old, who, in the course of a severe cold, developed osteo-myelitis foci in a rib and tibia synchronously; these were followed in the next three months by foci in six other bones. The infecting organism was not mentioned. Even this case comes on the border-line between youth and manhood.

Moreover, the case is noteworthy from the bacteriologic standpoint also. Lexer[1] in his exhaustive article (1896-1897) collected only 20 cases of osteo-myelitis in which the streptococcus was the infecting organism; 10 of these had been previously reported to the French Surgical Congress by Lannelongue.[7] Lexer remarks that the streptococcus, like the staphylococcus, shows a marked tendency to develop in the bones of the young. Lannelongue's cases varied in age from 10 days to 13 years. Of Lexer's 10 cases 8 were under 14 years of age.

In the examination of the pus from 73 cases of osteo-myelitis Lannelongue and Achard[8] found the streptococcus alone only 7 times.

Lexer has demonstrated that the clinical course of cases of streptococcus osteo-myelitis may not be unlike that of a staphylococcus infection. He divided streptococcus infections into three groups, in the first of which—containing those cases in which phlegmon was very marked in the affected bone and sequestration was found—the present case falls. Clinically it does not differ in any important item from the cases caused by the staphylococcus. Before Lexer wrote his paper Lannelongue had recognized a difference both clinically and anatomically between the streptococcus and the staphylococcus infections, and the symptomatology of the present case illustrates the fact (mentioned by Lannelongue) that both the fever and the pain in the streptococcus cases are apt to disappear on the third or fourth day. The improvement, however, is only temporary. Both symptoms return again.

It seems to be generally agreed that the pus in streptococcus cases is thinner and the necrosis of bone and soft parts less than in the cases of staphylococcus infection.

Klemm[9] says that a widespread phelgmon of the medulla is rare in streptococcus cases and that edema of the soft parts is of wide extent. Because a single case can not be maintained as the standard, the fact that the pus in the present case was thick and that the medulla was widely involved is of no particular importance. Besides, secondary infection was present at the time I first saw the case.

But let the clinical or the pathologic or the bacteriologic aspects and differences be as important as they may, the fact remains that the important and imperative thing, the factor that means most to us and to the patient, is an early diagnosis. An early operation must follow an early diagnosis. The old principle of "Where there is pus, open and drain" holds here. Pus is in the medullary cavity and it is the medullary cavity

in the acute cases that must be opened and drained, that results may be achieved. Doing less than this is doing nothing. Temporizing, when a diagnosis has once been made, is criminal.

DISCUSSION

ON THE PAPERS OF DRS. BOTTOMLEY AND NICHOLS.*

DR. DE FOREST WILLARD, Philadelphia—It is not only the ordinary practitioner who is dilatory in diagnosis, but there are many surgeons who are slow in making up their minds and the golden opportunity is lost. Every case of osteomyelitis is infective, and we know that it needs as prompt attention as does a case of acute appendicitis. It should be recognized in the first forty-eight hours; it should be operated on in the first forty-eight hours. It should be operated on as soon as the diagnosis is made, whether it be of a streptococcus infection or a staphylococcus infection, and therein I would differ with Dr. Bottomley. In regard to the infection: I believe that the streptococcus infection is particularly serious, but in either case cutting inside the medullary cavity of the bone, freeing it from pressure and from infective elements is the only method which promises relief from total, or large destruction of tissue. The ordinary practitioner, and still less the surgeon, ought not to allow these cases to go on to destruction, suppuration and death. These cases are practically dying from sepsis when they come into our hands, and they have been treated for what? For that bane of progressive medicine, "rheumatism." If we could strike the term rheumatism out of the surgical world, it would be a blessing. One of the most potent destroyers of men, women and children is that cloak of ignorance, inattention and neglect, "rheumatism." How many cases we see dying day by day with an abscess containing ounces of pus, and the physician still treating it for rheumatism, or for typhoid fever. This is not an uncommon thing—every surgeon sees it over and over again. What is most needed is early, correct diagnosis. The treatment is plainly indicated. Where we have the evidences of rapid infection, with increasing pain, and deep-seated tenderness, there is only one rational treatment, that is to operate at once, relieve pressure and establish thorough drainage from the medullary cavity of the bone. The opening can not be made too quickly or too freely.

DR. J. CLARK STEWART, Minneapolis—I think it is most opportune that these papers should have been read to-day, because we have been hearing so much of the various forms of abdominal surgery, particularly that of ulcer of the stomach, gall-bladder disease and appendicitis, while it is rare to hear papers on osteomyelitis. I overheard a remark while in my seat, which I hope the gentleman who made it will pardon my repeating. When Dr. Nichols took the stage he said, "What, another paper on osteomyelitis; they must have a great deal of osteomyelitis in Boston," which reminded me of Dr. Oschner's story in regard to gall-bladder disease in Rochester, and I think that Dr. Nichols might answer very much in the same way that Dr. Mayo did: "We diagnose our cases of osteomyelitis in Boston." I think, without doubt, that osteomyelitis occurs in the practice of every man here, and possibly oftener than he recognizes, and there is no question that a very large percentage of the cases are primarily diagnosed erroneously. The diagnosis of these cases as rheumatism, which Dr. Willard mentioned, is probably the commonest error made, this being especially true of the subacute and chronic cases. Among the acute cases the diagnosis of typhoid is often made, and this error is a very serious one in causing delayed treatment. It has been my lot to see several cases treated in a general hospital as typhoid until the abscess presented at some external point, and this, of course, has not the excuse of the same diagnostic error earlier in the history of the case when severe sepsis may so mask the local symptoms as to make the resemblance to typhoid quite striking. The leucocytic count ought to clear up all these obscure cases, as there is regularly a decided leucocytosis in all acute cases of osteomyelitis. The early diagnosis of osteomyelitis is unquestionably the important point, and with the facilities at our command ought to be made in most cases without great difficulty. In the subacute and chronic cases the difficulty of diagnosis is very much greater, and frequently there is no diagnosis made until a bone lesion is discovered at the bottom of the superficial abscess cavity. Fortunately, in these forms early operation is not of so great importance as in the acute cases. In regard to Dr. Nichols' paper there were two or three points in which I was particularly interested. One was the instruction that in early operations you should cut in the medullary cavity and drain the bone without interfering with the marrow. This seems to me dangerous as a general rule, for while I have no doubt that in many cases operated on early, one is able to say whether or not marrow is infected, still judging from my own experience there are cases with multiple foci scattered through the marrow where it would be extremely difficult without removal of the marrow itself to determine the limit of the infection. In regard to Cushing's operation for the removal of the whole bone, it seems to me that this is unnecessarily severe and liable to misuse, for there are a great many cases of partial osteomyelitis in which a much less extensive operation will secure perfectly satisfactory results. In many cases you can remove the sequestrum, clean out the cavity and get primary union by organization of a blood clot, and in other cases by the slower method of packing, the final results are very satisfactory. Personally, I have had very little experience with the Cushing operation, and the results which he reports in cases of total necrosis are certainly very brilliant, but I doubt whether it should displace the other methods which have stood the trial of time.

DR. RICHARD H. GIBBONS, Scranton, Pa.—Those of us who have been taught by William T. Detmold, James R. Wood, Thomas M. Marco of New York, and D. Hayes Agnew, the Grosses and our distinguished ex-chairman and teacher, Dr. Willard, need not fail to make a diagnosis of osteomyelitis nowadays, or in much earlier times. When I first began practicing medicine, thirty years ago, Detmold taught that pain of a dull character in bone was due to one of two causes, either syphilis, or inflammation that would result in abscess. If syphilis, one will get pitting on pressure over the tibia, whether there is inflammation or not, or how extensive it may be, whereas you will get but slight pitting if due to non-syphilitic inflammation of bone. Long since, I have been applying to suspected bone the test which the dentist applies to the questionable tooth. As Dr. Murphy has said, you will not get pain by pressure, unless it is long-continued, but you will get pain by percussive pressure. However slight it may be, you will get painful response by this method, even in the first hour of the attack. The thing to do before opening up or trephining inflamed bone is to locate the seat of the infection, by gently tapping over its supposed site. I have had considerable experience in this kind of work in the anthracite coal regions of Pennsylvania, where many of the boys engaged in and about the mines become infected, and I have chiseled out bone throughout its length, and I have never had a bad effect, although I chiseled the bone all the way from the head of the tibia to the ankle joint. In one case I trephined and then guttered the entire bone, down into the maleolus. This was in an old man, and he recovered. These cases ought to all get well by operation, promptly performed, unless there is a tubercular infection in connection with the trouble.

DR. J. B. MURPHY, Chicago—I wish to congratulate the gentlemen on the practical points in the papers, and I wish to speak particularly on the second paper; I desire to still more forcibly emphasize the point of early diagnosis in acute infec-

* Because of its length Dr. Nichol's paper will be published later.

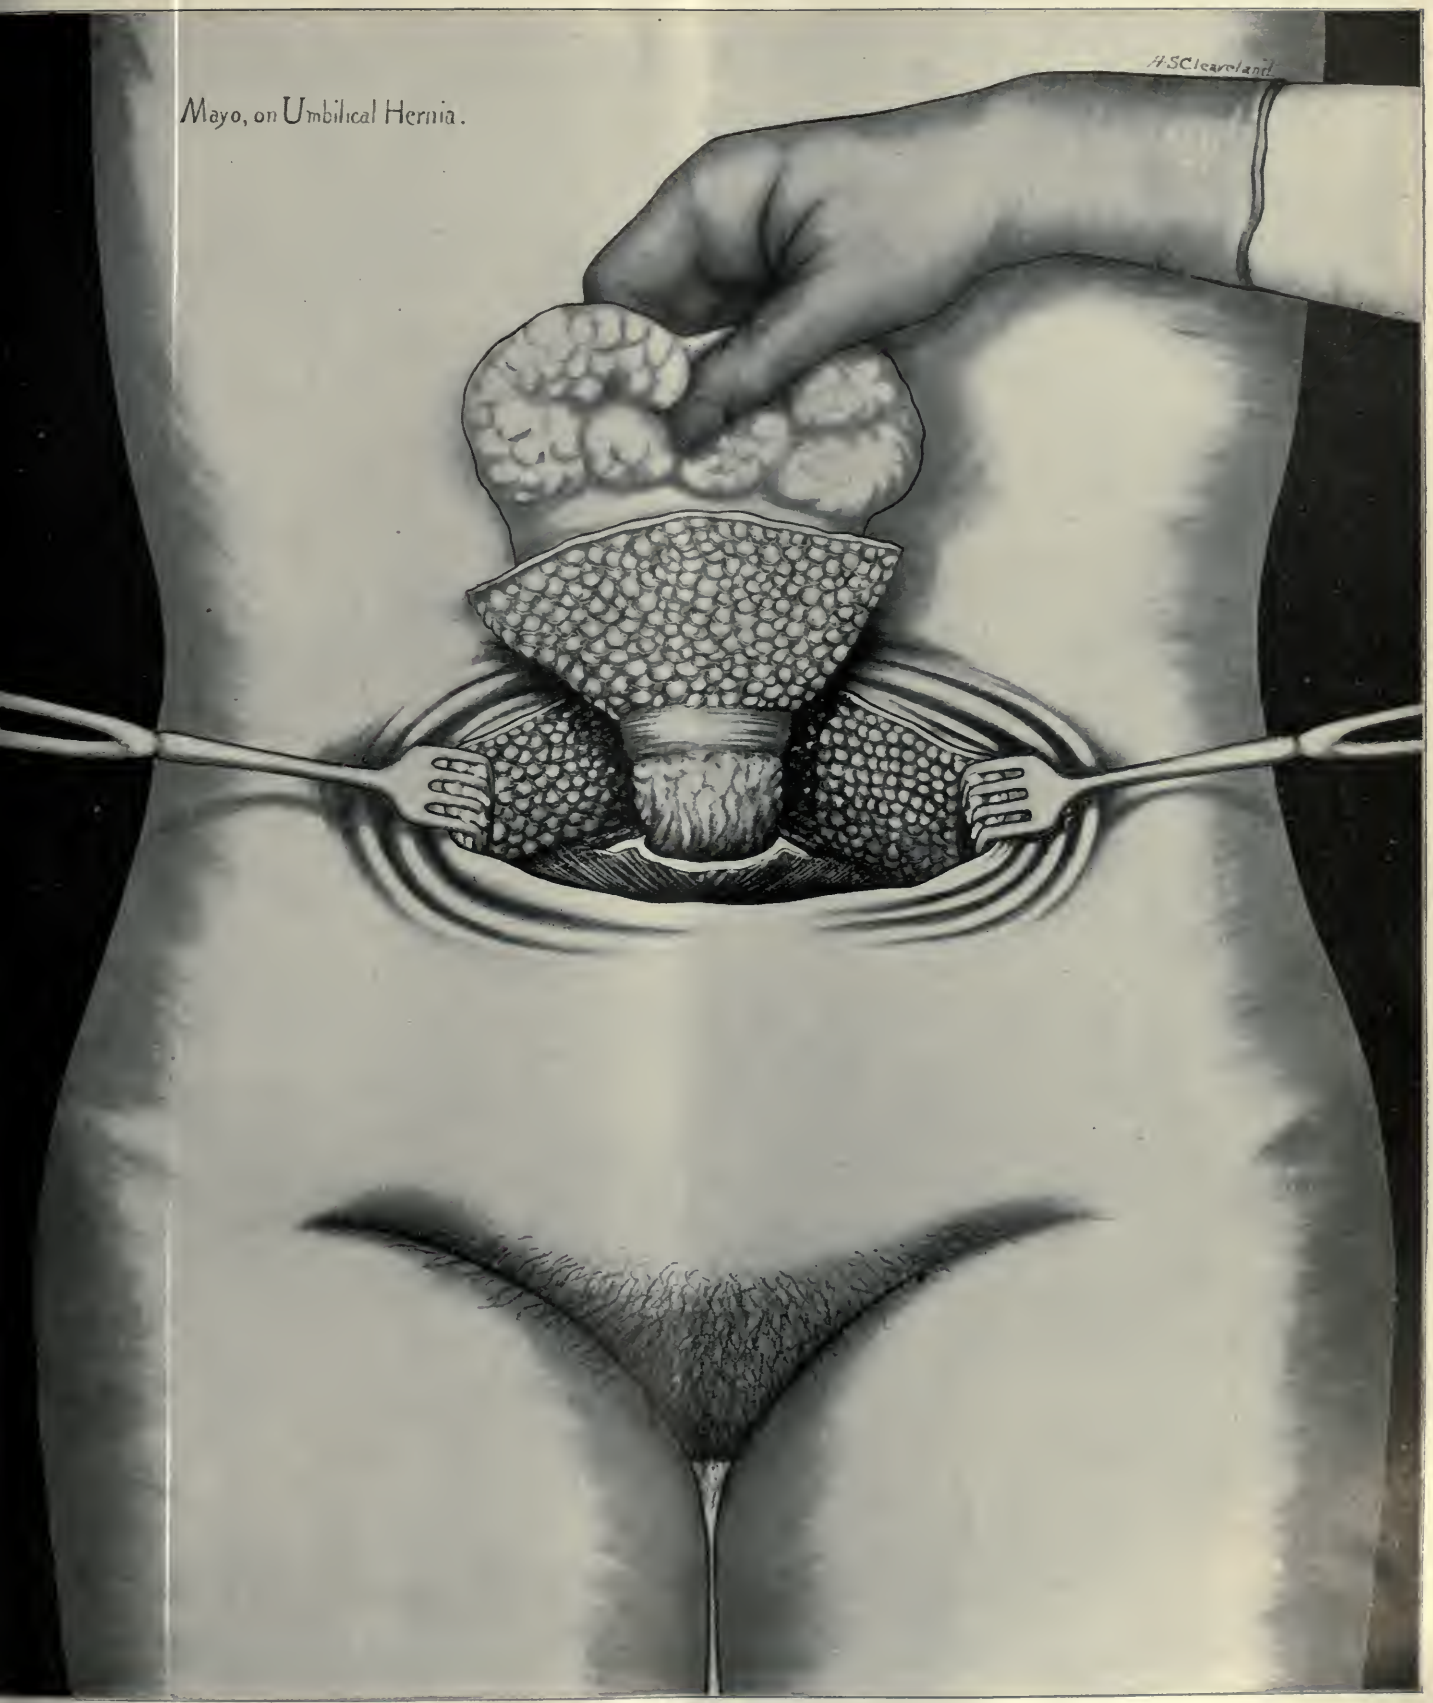

Figure 1.

Figure 2.

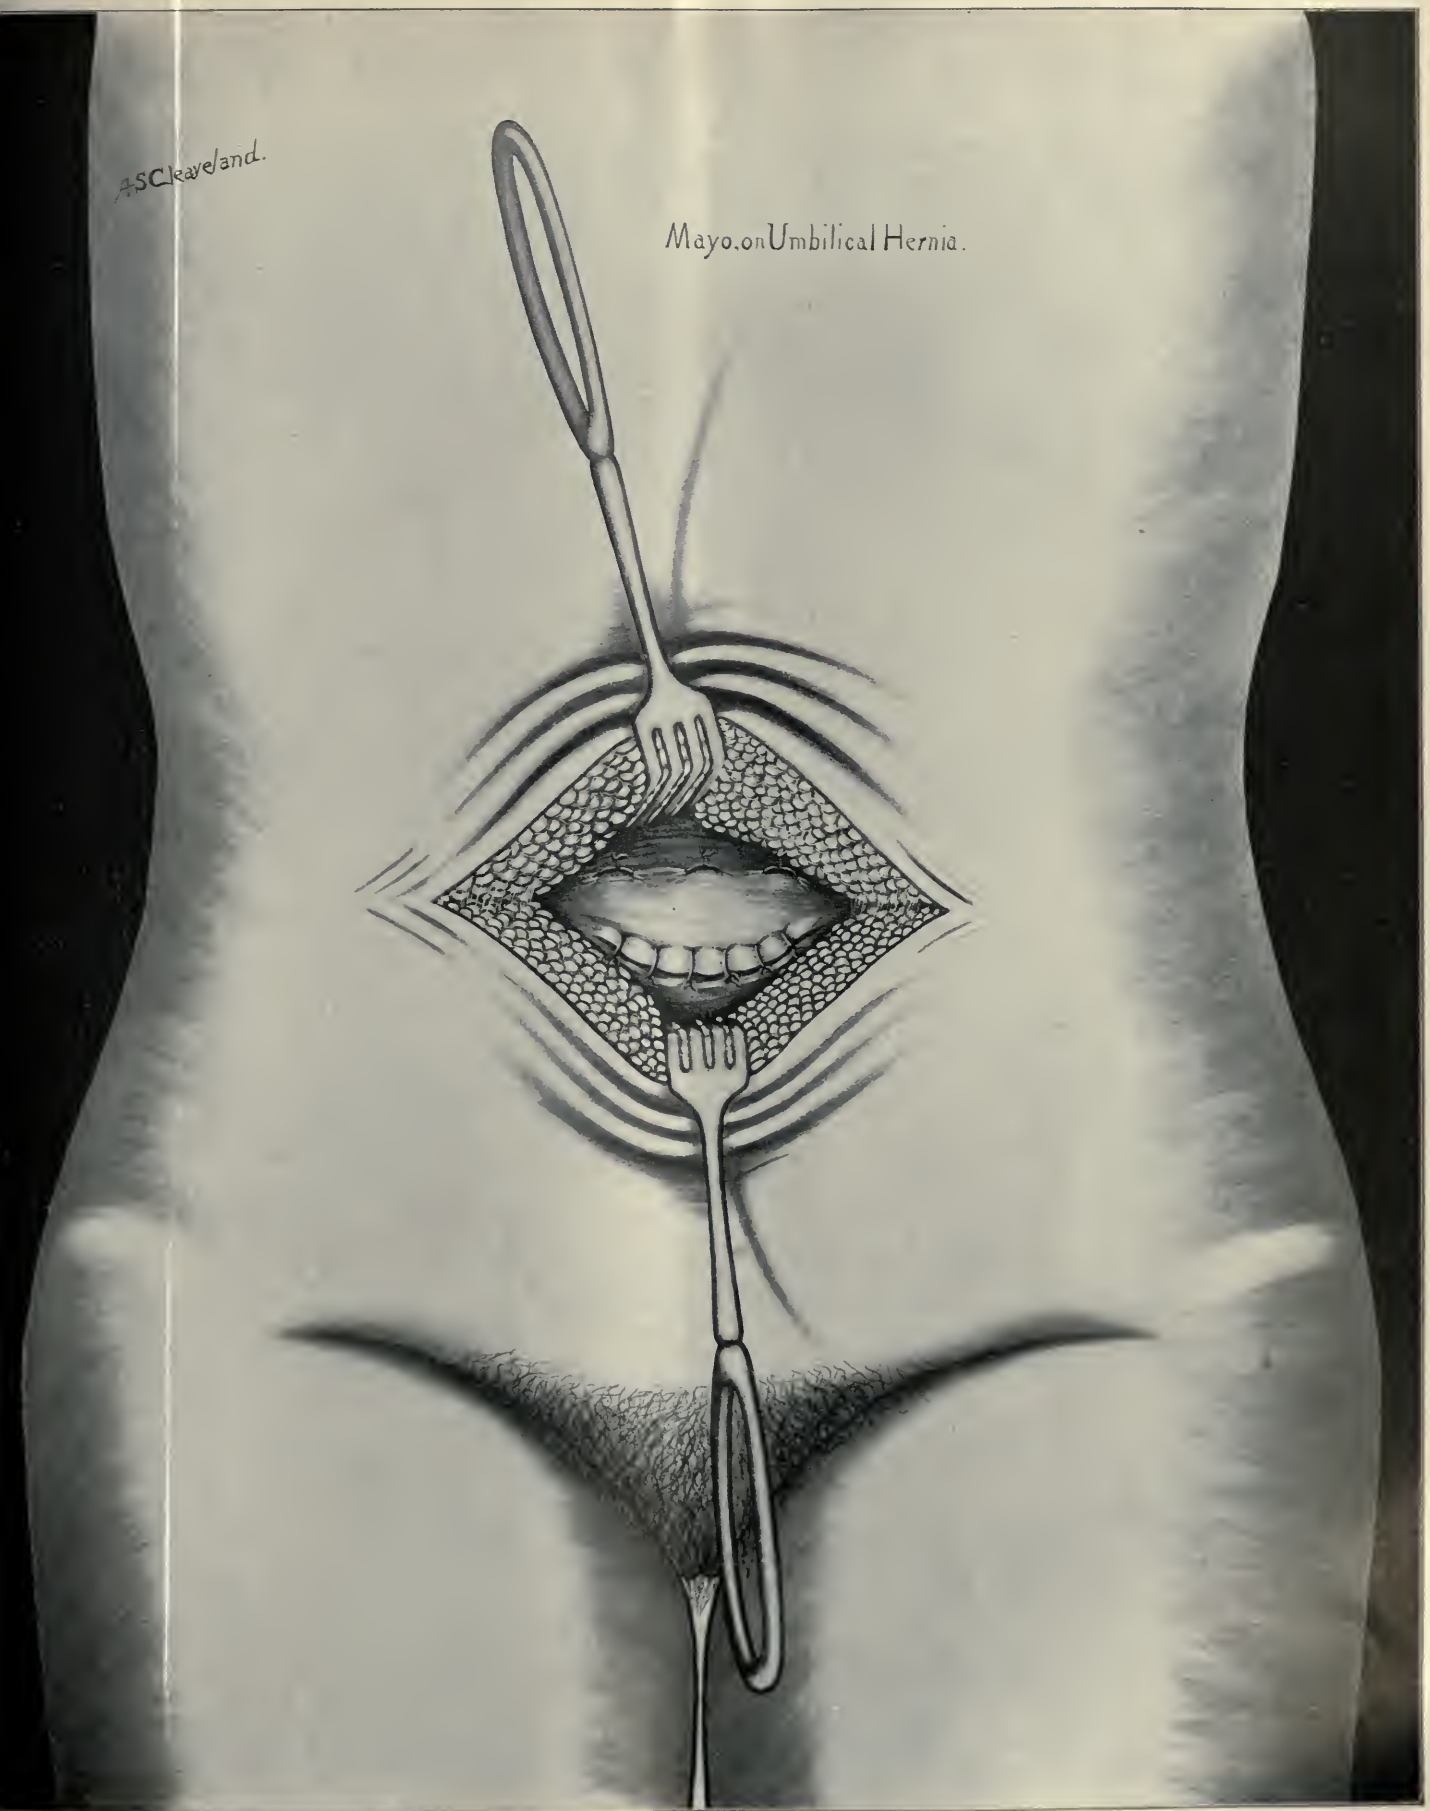

Figure 3.

tive osteomyelitis. What do we mean by early diagnosis in acute infective osteomyelitis? In what way is the physician of importance to his patients in a case of acute osteomyelitis? He is of importance to his patient in only one way, and that is when he makes a diagnosis inside of the first forty-eight hours. He is only of value to the patient when the case is diagnosed and operated on inside of the first forty-eight hours. Can it be done? Yes. The history of a case of osteomyelitis is so classic, so typical and so uniform that one can make the diagnosis ten hours after infection has occurred, or ten years, by interrogating an individual who was present at the time of the infection. What is the order of symptoms? The acute pain is usually preceded by a chill, followed by high temperature. The pain occurs usually in the extremities of the long bones, and in the majority of cases in children is not associated during the first forty-eight hours with effusion into the joint close to the focus of the disease, differing in this particular from rheumatism, which it is so uniformly erroneously diagnosed. The pain and sepsis increase hourly, but there is no local sensitiveness. Now then, what takes place in the third twenty-four hours after the infection? It is purely a symptomatic expression of pathology. During this period there occurs septic intoxication, acute absorption, high temperature, delirium, and all that goes with it. And with the advance of pathologic changes, with the increase of infectious products, with increasing pressure within the medulla of the bone from the bacterial invasion, we have destruction of the bone tissue, both by the toxic and biotic action of the infective flora, acting under great pressure. Rapid absorption continues until there is destruction of a vessel in one of the Haversian canals and the escape of the pus into the subperiosteal space. In the early stages of a case of acute osteomyelitis, there are no signs of inflammation on superficial pressure over the bone. I mean, during the first forty-eight hours, while the infective material is confined and restricted by the bony wall. In the third day of the infection, we usually have an escape of the pus from the center to the subperiosteal space, and sensitiveness to superficial pressure. But there is a sign that is an important one from a practical standpoint in the early stages; deep and continued pressure elicits pain and frequently indicates the position of the infection, even while the infection is still entirely within the bony wall. This will aid in making the diagnosis of the location of the focus of the infection. When the pus elevates the peritoneum, there is rapid necrosis as the circulation is cut off from without and within. In forty-eight hours one may have complete destruction of the entire shaft of the bone. Therefore, if we are to be of service and beneficial to the patient, we must relieve that infection focus from the condition which is so dangerous in any tissue of the body, namely, infection under pressure, by making an incision down into the bone and allow the infective material to escaps and thus avoid necrosis. We have just as perfect a guide to the source of infection as we find in many other cases of infection. One should drill a hole through the bone into the seat of the infection and allow the pus to escape from the bone, and thus relieve the intoxication and avoid necrosis.

If the general surgeon will get that window in the bone inside of the first forty-eight hours, he will save the patient from destruction of the bone, from the possibility of involvement of the joint, from the danger of fatal sepsis, and put him in condition for the line of demarcation to form, so that he will have but one small sequestrum. Then the case goes on and gets well, and the dead bone is easily removed through this window, after the separation of the sequestrum, usualy in six weeks. Chills, high temperature, local aching and no sensitiveness in the first forty-eight hours, except on deep and continued pressure for one or two minutes, when the pain becomes excruciating, are very strongly in favor of acute osteomyelitis and demands as prompt surgical intervention as acute infectious peritonitis.

DR. EDWARD H. NICHOLS, Boston—One or two points brought out in the discussion deserve some mention.

As regards the question of diagnosis: during the past five years I have had an opportunity to see many of these cases during the acute stage, at the Boston City Hospital, both on my own service and on that of the other surgeons, who have kindly allowed me to see their cases, and I quite agree with all that Dr. Murphy says in regard to the desirability of early diagnosis, if we are to expect the best results. I do not agree, however, that the early diagnosis always is easily made. In some of the cases the typhoid symptoms come on so early that the patient is too stupid to notice the pain, and the cases may be treated as typhoid fever by excellent diagnosticians. In other cases the joint pain and swelling may be so extreme as to entirely obscure the bone affection, although monarticular pain, especially in children, always should arouse at least a suspicion of osteomyelitis.

In regard to the reparative power of the marrow: the integrity of the cortical bone is dependent on the integrity, both of the periosteum and of the endosteum. Extensive stripping of the periosteum usually produces considerable necrosis of the cortex; if the endosteum also is destroyed marked necrosis of the cortex is certain. Thence if one trephines into infected marrow and curettes out the remnant of undestroyed endosteum he destroys the membrane which, in some cases at least, might regenerate the infected marrow, and maintain the integrity of the inner layer of the cortex. No one would, of course, remove the periosteum because he found an abscess between it and the shaft, and the same thing applies to the removal of the endosteum.

In regard to the removal of the necrotic shaft. It is not always necessary to remove the entire diaphysis. It may be sufficient to remove one half, or whatever portion of the diaphysis is necrotic. The removal of the entire diameter of the necrotic shaft is, however, much preferable to removing merely a shell of apparently necrotic cortex. When a mere shell of cortex only is removed it will be found, if the cases are followed for a number of years, that recurrences take place in a large majority of cases, and permanent cures are not common. The cases where removal of a superficial shell gives a permanent cure are usually cases of periostitis with little involvement of the marrow.

FURTHER EXPERIENCE WITH THE VERTICAL OVERLAPPING OPERATION FOR THE RADICAL CURE OF UMBILICAL HERNIA.*

WILLIAM J. MAYO, A.M. M.D.
SURGEON TO ST. MARY'S HOSPITAL.
ROCHESTER, MINN.

The results of operations for the radical cure of umbilical herniæ in adults have, heretofore, not been encouraging. These patients are usually obese, with attenuated abdominal muscles, and the thin, rigid character of the ring does not offer mechanical conditions advantageous to lasting union.

The principles of closure have been the same as after an ordinary abdominal section, the object being to split the fascia at the ring margins laterally, until the recti muscles are reached, and then, by a series of buried sutures, to reconstruct the abdominal wall in layers. The defect in this method is the natural separation of the recti muscles at the level of the umbilicus. Below this point the muscular structures are practically in contact, but above there is from one-fourth to three-fourths of an inch separation. To bring the recti together in this locality amounts to a muscle transplantation. In a small hernia this muscular approximation is not difficult, and is the operation of choice, but in the larger openings an inch or more in diameter, it is impracticable. and, so far as I have been able to judge, the attenuated muscles, when secured, are

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

not of great value as retentive agents in this variety of hernia. In very corpulent subjects the muscular separation is greater. If such a patient, lying on the back, be directed to rise, bringing into play the recti muscles, the lateral deviation at the level of the umbilicus is easily shown, and in the majority of cases demonstrates the impossibility of bringing them firmly into median apposition. The strain in these cases is from above downward rather than laterally. This is well shown by the pendulous abdomen commonly found in very adipose people, in many cases covering the pubes and often the region of the upper thighs. On assuming the recumbent posture the stretched tissues allow of great mobility and one can often grasp the abdominal wall and overlap a number of inches without difficulty. The fibrous margins of the ring in umbilical hernia usually lie entirely above the junction of the urachus and the remains of the hypogastric arteries. These latter structures, as they deviate from the middle line below, often allow of the formation of considerable pouches between them and the urachus, showing their weight-bearing function.

The causation of acquired umbilical hernia can be said to depend on downward traction of the abdominal walls and their contents brought to bear on a fixed point at the umbilicus, causing separation, and before this takes place there is an increased vertical lengthening of the abdominal wall and also, to a less extent, in a lateral direction.

In a paper[1] read before the American Academy of Railway Surgeons, Oct. 4, 1898, I called attention to the impracticability of covering in the defect, left by excision of the larger umbilical hernia, with muscle, and advocated the overlapping of the aponeurotic structures which were already at hand, securing a wide area of adhesions in place of edge-to-edge union. This method we had then employed in five cases; in three the overlapping was from side to side, and in two from above downward. Extensive lateral incisions to find sufficient muscle to make the routine operation described by surgical writers compelled us, as a matter of necessity, to overlap from above downward in these two cases and, to our satisfaction, we found the parts came together with less tension than when drawn laterally, and time proved that the strength of union was as lasting.

The first of these overlapping operations was done in 1895. We have now made this operation 35 times, overlapping from side to side 10 times, and 25 times from above downward. There were no deaths. We have found the operation so much easier from above downward that we now employ it exclusively. We have recently had the majority of these cases examined and the permanency of cure was most gratifying; in only one case had there been a relapse, and in this one there was merely a boat-shaped stretching. The operation had been done from side to side, and the patient was much relieved from her former condition. So far as we could find out, there were no failures when the vertical overlapping had been properly accomplished. In a paper[2] on this subject read before the American Surgical Association, May, 1901, I again called attention to this method. Further experience with the operation, as well as good results in the hands of other members of the profession, has more than ever convinced me of its value. Writers on this subject deplore the poor results of operation for this variety of hernia and even the latest compilations speak most disparagingly as to the permanency of cure by any method, and this was previously our experience. To-day the expectation of cure approaches that of inguinal hernia. The operation is easily and quickly performed. The steps are as follows:

1. Transverse elliptical incisions are made surrounding the umbilicus and hernia; this is deepened to the base of the hernial protrusion.

2. The surfaces of the aponeurotic structures are carefully cleared two and a half to three inches in all directions from the neck of the sac.

3. The fibrous and peritoneal coverings of the hernia are divided in a circular manner at the neck, exposing its contents. If intestinal viscera are present, the adhesions are separated and restitution made. The contained omentum is ligated and removed with the entire sac of the hernia and without tedious dissection of the adherent portion of omenta.

4. An incision is made through the aponeurotic and peritoneal structures of the ring extending one inch or less transversely to each side, and the peritoneum is separated from the under surface of the upper of the two flaps thus formed.

5. Beginning from two to two and one-half inches above the margin of the upper flap, three to four mattress sutures of silk or other permanent material are introduced, the loop firmly grasping the upper margin of the lower flap; sufficient traction is made on these sutures to enable peritoneal approximation with running suture of catgut. The mattress sutures are then drawn into position, sliding the entire lower flap into the pocket previously formed between the aponeurosis and the peritoneum above.

6. The free margin of the upper flap is fixed by catgut sutures to the surface of the aponeurosis below, and the superficial incision closed in the usual manner. In the larger herniæ the incision through the fibrous coverings of the sac may be made somewhat above the base, thereby increasing the amount of tissue to be used in the overlapping process.

In very large protrusions in which part of the hernial contents is irreducible the patient should be kept in bed on a reduced diet and directed to manipulate the hernia, with the intention of replacing as much as possible. The irreducible portion must not be forced into the abdominal cavity after losing the "right of habitation." If of omentum only, it is readily disposed of by excision; if intestine, enough omentum previously contained in the peritoneal cavity should be removed to allow of reduction of the bowel without pressure. The patients should be kept in bed three to four weeks after operation and, after getting about, should not apply a truss, although most of these patients prefer to wear an abdominal supporter for a year. Piccoli[3] reports a case successfully operated on in August, 1899, after the lateral plan, and refers to a case reported by Bonomo, operated on Dec. 9, 1899, with a favorable result. J. A. Blake[4] reports several cases operated on by the lateral method during the year 1900, and refers to an article by Sapiejko,[5] in which a lateral operation is described.

The writer had described and operated by the lateral overlapping plan several years before the cases reported by these authors and the lateral operation is a good operation, but it is not as good as the vertical method, in which the retaining structures are given a bearing point above the site of the umbilicus and intra-abdominal pressure thus acts to prevent separation instead of aiding it.

DISCUSSION.

DR. A. J. OCHSNER, Chicago—The fact that with but a few exceptions every text-book on surgery, and every book dealing with the question of hernia, claims for the radical cure of umbilical hernia: First, a large mortality; and second, a large proportion of recurrences, makes this paper of especial value to this Association.

The writers of these works have no appreciation whatever of the proper treatment of umbilical hernia. One of the most distinguished authors on the subject of herniotomy told me personally only a few months ago that he operated on these cases only when he was absolutely compelled to, simply because he did not know how to operate on them. As a matter of fact the reason there is a high mortality in these cases is because of the extreme and unnecessary traumatism occasioned by the ordinary operation. The ordinary operation contains at least ten times as much traumatism as is necessary. The operation usually described in text-books contemplates the establishment of conditions very similar to those which were present before the umbilical hernia was produced. The fact that those conditions were unfavorable for a permanent cure is shown by the fact that the umbilical hernia occurred. Statistics show that umbilical hernia in children heals spontaneously in nearly 100 per cent. of all cases, simply because it is impossible to keep a circular opening in any part of the body open, unless it is lined with a serous or an epithelial lining. So long as the opening is kept circular it will heal spontaneously. We find in all of these cases in the adult that there is a dragging of the abdominal wall transversely, causing the opening to assume an elliptical form. Then we find that the preperitoneal fat is forced up into this opening, the consequence being that the hernia occurs. To relieve this condition, we know that we can establish a condition very similar to the linea alba. We have the aponeuroses of the external oblique, the internal oblique and the transversalis muscles; we can make use of these, but we should not do so in such a manner as will prevent their drawing from side to side. This can be accomplished by the operation described by Dr. Mayo. In this manner the greater the tension on the abdominal wall the more firmly the hernial opening becomes closed. That is the reason he does not get recurrences. If the patient vomits, the more he vomits the tighter the wound is closed. I had the good fortune of learning this trick from Dr. Mayo several years ago. I have operated nearly as many times as he has, but I always closed the wound from above downward. In one-third of his cases he made the same mistake that Blake and the other gentlemen made who have described similar operations, but who overlapped the edges from side to side instead of from above downward.

The great advantage in this operation does not only come from the fact that the strong fascial layers are doubled but also from the fact that the deformity which always exists in these cases, namely, the shortening of the transverse circumference at the level of the umbilicus and the lengthening of the distance between the sternum and the pubis, is utilized to advantage.

DR. J. B. MURPHY, Chicago—It is a particular pleasure for me to discuss a paper on umbilical hernia, because I have had some misfortunes. I was very much surprised at the close of my clinic one day to have a visiting physician ask me if a case of umbilical hernia ever got well. That was an actual occurrence. He had just visited several other celebrated clinics and he said that all the cases he had seen operated on there died. It frightened me, and that very day the patient whom I had operated on died. That caused me to make some investigations and to ask some questions and it led me to visit Dr. Mayo and observe him do this work. My particular patient died from one of the causes that is cured by just this operation, and I believe that many of the other deaths have resulted from just this same cause, because in looking up the literature you will find that most of them died shortly after the operation. My patient died of pulmonary edema. In doing the lateral operation, the tension put on the suture incapacitates the patient for diaphragmatic breathing and the patient has an edema beginning shortly after the operation, and if the irritation is sufficient, in one, two or three hours after the patient has recovered from the anesthetic, you will see him panting for breath. It was my extreme pleasure, after doing the first operation by this method, to see that the patient was vomiting without even the slightest distress at the seat of the wound, and the reason for that is the excellent mechanical application, the one applied on the other, giving such perfect support that there is no tension on an edge-to-edge suture. I feel that the question of umbilical hernia is solved primarily and finally by this very simple, complete and perfect operation.

DR. WM. H. WATHEN, Louisville, Ky.—If we perform the operation for umbilical hernia, as outlined by Dr. Mayo, we have no bad results following the operation, and then consider the previous methods in vogue for this procedure and the high mortality following them, we will come to the conclusion that there is no operation which has more simplicity about it, or which may be performed with less mortality and with better results. Since I saw the report of Dr. Mayo's first operation, I have been performing it, and find it practically universally successful. About a year and a half ago, a lady consulted me, who was so large and fat over the abdomen that certainly no surgeon would have undertaken the operation after the old method, the hernia being very large, with many adhesions. She was operated on by the transverse overlapping method, taking away a very large piece of fat, and recovered without pus or temperature. She now has an abdomen changed in shape, and is perfectly well in every particular. I have had no trouble in these cases during the operation or subsequent thereto.

If I understood Dr. Oschner correctly, he said that the great success in these operations was due to the fact that it shortened, or contracted the transverse diameter, and elongated the abdomen longitudinally. Well that is what may occur in the old vertical method, but not in the overlapping transverse method. You shorten the abdomen vertically. The pressure transversely cannot pull the surfaces apart, and the patient continues to get well.

DR. WILLIAM H. MAGIE, Duluth—I wish to endorse the operation of Dr. Mayo by reporting two cases of umbilical hernia that I have operated on during the past year. They were both very fat women, the hernias were of long standing, and the results so far have been very satisfactory. I have used the same method in operation for cures of ventral hernia resulting from surgical operations in the abdominal cavity.

DR. ALEX. H. FERGUSON, Chicago—A lateral operation for umbilical hernia is indicated in certain cases, and in others I would commend the operation worked out by Dr. Mayo. In either instance the procedure is a plastic one in which the surgeon makes the best use of the material at hand to most securely prevent a return of the hernia. When the opening is not very large, the recti muscles in good condition, the lateral operation gives excellent results, remembering that the muscles must be liberated and sutured in mid-line over the coapted peritoneum, and transversalis fascia. Any redundancy of the pendulous fat in the abdominal wall may be removed at the same time and greatly to the comfort of the patient. This I have done several times.

When, however, the opening is large it can be more easily closed by overlapping the structures from above downward and thereby obtain a very strong abdominal wall. But let me suggest an additional step which furnishes more strength to the umbilical region. That is to slit open the sheaths of the recti and bring them nearer together over the overlapped fibrous structures. This will leave these muscles in a position to protect by their contraction a weak place during sudden increased intra-abdominal pressure.

While I agree with Dr. Murphy that it is not a good thing to constrict the abdomen, still I should be inclined to attribute the cause of death in his case as due to something else.

DR. WILLIAM J. MAYO, Rochester, Minn.—In answer to a question I will say that we have removed the fat in two cases. I feel somewhat overcome by the remarks of Drs. Oehsner

and Murphy, and I think we must all take them as a joke. Dr. Ferguson has insisted on saying that this is the Mayo operation. My own feeling is that all this stuff about priority is bosh. I have no doubt that this operation was done by Hippocrates; he was a very sensible old fellow and quite likely, as they get in deeper in the Egyptian ruins, they will find that this operation was performed by the inhabitants several thousand years ago.

REPORT ON OPERATIVE TREATMENT OF GRAVES' DISEASE.*

T. C. WITHERSPOON, M.D.
ST. LOUIS.

CASE 1.—In April, 1895, a patient presented herself for treatment suffering from a well-developed Graves' disease. Exophthalmia was not marked, but the cardiac frequency and the thyroid enlargement was present. Tremor, loss of flesh and bowel symptoms made the case one of undoubted Graves' disease. She submitted to partial thyroidectomy under chloroform and made a nice recovery. Two years afterward I received word from her through a friend that she was well and strong, able to attend her duties and suffering none of the former symptoms.

CASE 2.—In 1898 a patient was sent me who suffered from a similar condition. She was 52 years of age, very thin, having lost a great many pounds of flesh, suffered from recurring diarrhea and was very weak, practically bed ridden. The pulse rate was 140 to 160, the thyroid very large and vascular, exophthalmia not marked. The right lobe being the larger was removed under cholorform anesthesia. There was very free hemorrhage from the inferior thyroid, and on account of pulse weakness she was given a pint of saline under the skin while on the table. This was repeated in two hours. Within six hours the pulse had regained the rate and quality which characterized it when she went on the table. During the night it began to increase in rate and lose in strength. There was no response to stimulants and in forty-eight hours she died.

CASE 3.—The third case on whom I operated was a woman 59 years of age. She was born in Missouri and had lived in St. Louis for many years. Her first visit to me was in September, 1899, at which time she suffered from very evident Graves' disease. The goiter was well marked, the right thyroid lobe being the larger, there was moderate exophthalmia and the pulse rate was from 130 to 150. She had lost a good deal of flesh, the skin was always moist because of an exhausting sweating, the nervous symptoms were marked, heard strange noises and had ideas of persecution; the respiratory movements were extremely shallow and pectorals wasted, bowels were diarrheic, urine contained casts and albumin, and was slightly increased in the 24 hour amount. A diagnosis was made of chronic interstitial nephritis associated with Graves' disease. I was of the opinion that her general condition contraindicated so extensive an operation as partial thyroidectomy and advised a double sympathectomy. September 10 the three ganglia on the right side were removed and on the 21st those of the left, under chloroform. The healing was primary and shortly after the second operation the pulse showed improvement in quality and rate. Her general condition was likewise benefited, the bowels ceased to become overactive, the sweating stopped, the weight improved. December 14 she had so far recovered that she took a trip into the country to take advantage of the fresh air and outdoor life possible there. From her son I learned later that in the latter part of the month of February while out riding she became chilled and died two hours afterward. He states the pulse rate had become normal before her death, the exophthalmia had almost entirely disappeared and the goiter fully half. Her mental condition was normal and the nervous symptoms had cleared up to a large extent. What part was played by the nephritis in her sudden death can, of course, be only a matter for conjecture, but it must be admitted the operation was followed by decided relief.

During the last twelve months I have had a series of six cases presented me for operation in all of which partial thyroidectomy was performed. They were as follows:

CASE 4.—About the first of May, 1902, S. S. was sent to me with a pronounced exophthalmic goiter. She had been under treatment without benefit and an operation was advised. She was born in Germany, came to St. Louis when 16 years of age, and has lived here since, a period of 23 years. There is nothing of note in her family history. At the time of her first pregnancy the thyroids became larger and remained so afterward. There were no symptoms of Graves' disease until about a year before I first saw her. At that time she noticed an increased nervousness and rapid heart action. At the time of the examination she had a well-marked exophthalmia and stated that the intensification of the symptoms dated back five months, at which time she became pregnant. Her general condition indicated a process of only moderate severity. There was not a great loss of flesh and her appetite and strength were fair. She did suffer from a marked degree of nervousness, however, and insomnia was distressing. The pulse rate varied from 100 to 120, exophthalmia marked, Graefe symptom present, the right thyroid lobe the larger. Other symptoms were present, as tremor, sweating, headache, recurring diarrhea. She had had attacks which resembled asthma for years, and these had been intensified.

May 6 the right lobe was removed under local anesthesia. After finishing the operation and while putting on the dressing she had a slight tetanic attack, general in character and accompanied with a loss of consciousness for the moment. No ill effects followed this, and after being placed in bed she felt quite easy, except for a mild degree of burning in the area of the wound. This lasted only two hours and disappeared. The improvement in her condition was apparent in two days, and within the next week she was fairly free from nervousness. The pulse dropped to 74 in forty-eight hours. There was rapid improvement in the exophthalmic condition also. During the remaining time of pregnancy she showed only such symptoms as are characteristic of the period. She was delivered at full time of a healthy child, making a nice recovery herself. At the present writing her condition is quite normal.

CASE 5.—Mrs. B. came to me in June presenting the following history and conditions: Born in St. Louis, lived here all her life, 35 years, parents were German, she was married some years, but had no children; examination revealed no pelvic disturbance. Gives no family history which could shed light on her trouble. About nine months before coming to me she noticed the first marked symptoms of her present disease, although for some months prior to that time she had noticed an increased nervousness and a tendency to tremble when using the hands. I found on examination well-developed thyroids, larger on right side, pulse varied from 120 to 130, exophthalmia marked and Graefe and Moebius symptoms were demonstrable. The other symptoms were present, tremor of the hands, diarrheas, sweating, loss of flesh, sleeplessness, easily excited, headaches, dry hair coming out in rather large quantities. The right vessels gave both a distinct bruit. An interesting feature was the pronounced prominence of the left eye.

The right lobe was removed under local anesthesia and betterment of the condition immediately followed. At the present time all of the old symptoms have disappeared, including the exophthalmia. She has gained in flesh and feels well.

CASE 6.—In July I removed the right thyroid lobe of a patient in one of the city institutions. She presented the usual symptoms and had in addition a movable right kidney and slight uterine prolapse. After the operation she made a rapid recovery, sleeping well, no tremor and gaining in strength. After leaving the institution I lost track of her.

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. A. J. Ochsner, J. E. Moore and De Forest Willard.

CASE 7.—Mrs. W., age 62, born in Switzerland, lived in St. Louis eighteen years, was sent to me in July for an operation. There was no family history of importance except that a daughter of 36 years of age has at the present time a simple goiter. She had a goiter herself for twenty years, during which time there was no indication of trouble from it. The symptoms of Graves' disease dates from the time of the death of her child three years ago. This daughter died of tuberculosis. In January, 1902, she suffered an attack of pneumonia, from which she did not fully recover. Effusion into the left pleura followed it and on May 17 three pints of this was removed. Again on the 27th this was repeated, removing the same amount. The physician in charge at the time reported on the character of this fluid, stating it was not purulent nor bloody. The expectorate was likewise examined and found to contain no tubercle bacilli. At this time the symptoms of Graves' disease became very pronounced. The tremor marked, muscular weakness with emaciation sufficient to cause her to remain abed, insomnia, emotional perturbations, pulse varying in rate from 135 to 160, and frequent diarrheic attacks. The exophthalmia was not readily noticed unless attention was called to it.

The right thyroid lobe was the larger, and this one was removed July 20. It had grown downward into the chest behind the sternum and was adherent to the trachea for a short interval. The vessels were very friable and the forceps pinched through the inferior thyroid during the operation and bleeding became very active. This necessitated a haphazard catch, which included the inferior (recurrent laryngeal) nerve. Immediately a fluttering vocal cord was the result. In tying the vessel after stopping the hemorrhage it was carefully separated from its surroundings. The voice returned very slowly afterward, never to its normal quality. A pneumonia was set afoot, which appeared on the fifth day in the left lung, the seat of the former attack. Eventually this subsided in part and the patient began to improve. A careful examination still failed to reveal tuberculosis. In six weeks the nervous symptoms had nearly disappeared and the rate of heart action was between 90 and 100. There was a slight, constant fever and cough and the fluid reaccumulated in the side. On aspiration this was found to be purulent. An operation was strongly advised, but refused until late in October. By this time she had lost the flesh gained just after the operation on the thyroid and was very weak. The process had extended to the lung and a large quantity of stinking pus was being expectorated constantly. A portion of rib was removed under local anesthesia and a drain established. She never rallied, however, and died about Christmas last. There was a complete disappearance of those symptoms which were distinctly characteristic of the Graves' affections before her death.

CASE 8.—A widow, aged 44, born in Germany, came to St. Louis 16 years ago. She has one living child healthy. She gives no history of former trouble which could bear on the present trouble except that 18 years ago she contracted a venereal disease from her husband which confined her to the hospital for several months. The cervix of the uterus is entirely gone and a small opening in the midst of scar tissue is the os uteri. Menstruation is normal except scant in amount. She gives no history of syphilis. Her pulse varied from 95 to 110, some degree of exophthalmia, goiter goose egg in size, the right lobe the larger. A fine tremor, muscular weakness, diarrhea, sweating, nervousness, sleeplessness, headaches were present. I removed the right lobe of the thyroid in September. The pulse rate became normal after the operation, the general condition improved and the tremor left. She still suffers, however, from headache, fullness in the throat and complains of weight in the pelvis. This, I believe, is due to the uterine condition.

CASE 9.—Just operated on. Patient is 29 years of age, born in Kansas, and has lived in various parts of the country during the last ten years. Of herself she writes the following history, and because of its exactness I give it in full. Rather anemic looking since fifth year, scrawny shoulders and small arms. All through life frequent headaches in forehead. In sixteenth year moved to Colorado, living in altitudes of from 6,000 to 9,000 feet, where was employed as a railroad clerk for three years. Felt well greater part of the time. Eyes would occasionally become inflamed; riding on trains augmented this trouble. Vision was not impaired for three years after first inflammatory attack. About twentieth year moved to Memphis, Tenn., eyes becoming more often sore. Oculist advised against glasses and used some drops in eye for two months daily. Vision now became impaired, objects blurred, lines of type ran together. Saw another oculist, who fitted glasses, said trouble was flattened cornea. Wore these glasses with some relief for about a year, eyes gradually becoming worse; inflamed with imperfect vision. In twenty-fourth year another oculist fitted glasses, saying the trouble was compound myopic astigmatism with the consequent inflammation. Great relief followed; worn the glasses since with improved vision, inflammation lessened. Past three years has had many spells of aching back of left eye and followed by reddened conjunctiva. About the twenty-fourth year hand became unsteady when writing. During the summer months each year while in Memphis got debilitated and irritable. During the winter of the twenty-fifth year worked all day and until 11 o'clock at night. Kept up by large quantity of alcoholics. In spring of same year, 1899, passed first-class examination for old line life insurance. No enlargement of neck was noted at the time. Pulse was a trifle quick, attributed to running up stairs. During the summer became gloomy, brooded over unfair treatment thought she had received at the office where working. Spent month of July in St. Louis, read much pessimistic and agnostic literature. Thought a great deal about suicide, did not contemplate suicide, but the subject was more attractive than others. Returned to Memphis August of the same year in the same state of mind. Friends tried in every way to divert her mind into new channels without success. Again worked hard the fall and winter of the twenty-sixth year. Gradually mind became normal. December, 1899, noticed neck seemed to look too full in front, friends thought it was all right. In winter was tired all the time, sore and ached all over on awakening; very nervous and irritable. Hands and feet became swollen and red, burned and itched when taking exercise. For last three years perspired profusely on slightest exertion. Hands and face would be moist and clammy while those about were dry and comfortable. Did not sweat at night when quiet in bed. Hair became faded and dry, but did not fall out to any appreciable extent. During the summer of 1900 lost much flesh and became more nervous and weak. In the fall some improvement.

About Jan. 1, 1901, noticed rapid heart action and shortness of breath. Remained in bed for a part of February complaining of prostration, nervousness and insomnia. At this time the goiter became quite perceptible. Dr. R. Maury prescribed tr. iodin applications without benefit to the goiter. Massage was then resorted to for a month with no benefit. If anything this last increased the nervousness. The professor of nervous diseases at the Memphis Medical College then prescribed Norwoods tincture of veratrum viride, to be taken constantly and a mixture of hyoscyamus, potassium bromid and chloral to quiet. This latter was taken at bed time for two years. For the remaining time the bromid alone has been used to produce sleep (60 to 100 grs.).

Exophthalmia was noticed in June, 1901. At this time she gave up all stimulants, as they caused a sense of weakness and she had to go to bed after taking them. Later in same summer went to Lake Superior for a visit and improved remarkably, gaining 18 pounds. In fall relapsed into old condition on returning south. Complained at this time of having both knees give away while walking, causing her almost to fall at times. Arms and legs became numb after resting in one position for a while. Last summer spent at Put-in-Bay, but an exhausting diarrhea prevented improvement.

In fall went to Colorado, where nervousness and rapid heart increased and mental condition became worse than ever. Had maniacal spells, screamed, tore clothing and refused to remain in the room with any one. Physician in charge gave thyroids and strychnin, and if anything the symptoms were

intensified. Pulse was frequently as high as 150 and felt like a pile driver in the neck. Thyroid increased in size. Took 400 grains of bromid in two hours to quiet. Later returned to the chloral mixture and a tonic. During the last three months suffered from alternating diarrhea and constipation. Appetite fluctuated from a craving for food to a distaste for it. Limbs twitched in bed and insomnia continued. Sore around body and hung clothes from shoulder; temperature of 99 to 100 in the late afternoons. Has a cough which developed in December, 1901, and has continued more or less ever since. At menstrual periods the gland seems to become turgid and causes a sense of choking from pressure.

The only family history which could bear on this condition is on the mother's side. She had asthma until her sixteenth year, always had an affection of the right side of the mouth and jaw. Right lobe of thyroid slightly enlarged and had been so from childhood. Never had the other cardinal symptoms of Graves' disease. Mother of seven children, three died in infancy; one son and three daughters are living. Son as a child suffered from nervous twitching, is now 40 and healthy; daughter, aged 32, has writer's cramp at present, always nervous. Other daughter always free from nervousness. Mother in good health at present.

July 15, 1903.—This patient is in better health than for some time. Exophthalmia gone. Pulse 80 to 90.

These cases of Graves' disease have been in the past most unsatisfactory to treat. Nearly every effort to bring about permanent relief has been fruitless. We have all seen temporary benefit follow the administration of different remedial agents, and have been at times tempted to believe that much of permanent character had been accomplished, only to be disappointed later when, after losing sight of the patient for a while, they would return in a more deplorable condition than ever. Failure in this disease has, as in many other maladies, led to the adoption of a host of remedies for its cure.

It is exceedingly interesting to follow the views of the various writers of the different decades on the subject, and note the changes in the methods of treatment. We read of the disease being a dyscrasia, then, again, a blood impoverishment expressing itself by changes in the thyroid, eyes and heart; later the opinion of alimentary intoxication, a sympathetic disease or a pathologic condition of the central nervous system located in the area of the pons or medulla. Of the recent authoritative writers Moebius adheres to the belief that the seat of the lesion is in the thyroid gland, while Kocher, of Berne, considers the thyroid condition an expression of a central lesion located in the cerebrospinal axis. Mention should be made of the work done by Gley, of Paris, showing a disturbed parathyroid relation with the thyroid as a possible cause of the disease symptoms. As from time to time new light has been shed upon the subject, bringing modified ideas of its pathology, the methods of treatment have accordingly been modified or changed altogether. Iodin, strophanthus, veratrum viride, bromids and chloral, galvanism, thyroid extract, adrenalin, sodium phosphate, sodium salycilate, dietetic regulation, massage, the serum of thyroidectomized goats, the flesh and milk of these animals, and lastly, various surgical procedures, have each been advocated as most helpful.

Naturally, the question arises, what are we to do for, how are we to relieve this class of patients when they come to us for relief? Is there an underlying cause for the condition which can be attacked alike in each case, is there a procedure which could become universally applicable? In the light of our present knowledge we can not hold to too strict limitations, though no doubt were the exact nature of the disease known some rule of action would become applicable to all cases. At the present time a certain degree of empiricism must enter into the treatment; our conduct toward these cases must rest to a large extent on our experiences in the past. We must notice where the internist obtains good results, and weigh carefully the data he presents; likewise have we to consider the surgeon's side of the question, and noting here success and there failure, obtain an explanation of the different results by the different manners of operation, and the individual characteristics of the patients.

I present here the results which I have obtained in cases in which internal medicine failed to give relief. The outcome has been very satisfactory to me, and has helped very materially to lead me to the belief that these cases are eminently surgical. Since reading Kocher's article, this belief has been confirmed, and I feel enthusiastic in supporting proper surgical methods for the relief of Graves' disease. Of course, do not understand this to mean that I advocate operation in every case, regardless of all conditions, local or general. In the first place, we must be governed by those rules which are followed in advising operation on any part of the body for the various conditions which fall to the surgeon's hands. In the second place the symptoms which characterize Graves' disease must be given due consideration, and proper value placed on the conditions which characterize each individual case.

A number of surgical procedures have been proposed. The injection of agents into the gland which tend to destroy its secreting power is dangerous, and should never be resorted to.

Ligation of the thyroid arteries to reduce vascularity of the gland has a warm advocate in Kocher. This method was recommended by Woefller for the common goitre, but Kocher put it to use in the exophthalmic variety. Rehn, Trendelenburg, Rydygier, Wilmers, Reinbach and Mikulicz have reported cases treated in this way. Ligation of the superior thyroid is relatively easy, but the inferior can not be gotten at through an incision in front of the sternocleidomastoid, except by luxating the gland upon the surface, in many of the cases. In selecting the vessels, attention will be paid to the amount of vascular degeneration of the different parts of the gland. It is rare that the whole gland is alike affected. Those vessels are ligated which best control the vascularity. The operation is simpler than removing the lobe, and is to be recommended in those cases where the symptoms remain intense after resting the patient. Later, however, this procedure should be supplemented by a partial thyroidectomy in the large percent of cases. The initial ligation always renders the removal of the lobe easier than where this is done primarily.

Unquestionably, the operation which gives the greatest degree of satisfaction is the removal of the most involved lobe of the thyroid gland. Very frequently this is the right. Why this should be so is difficult to understand. Many explanations have been given, but none satisfactory. Two incisions are to be recommended, one in front of the sternocleidomastoid parallel to its anterior border, and the U-incision recommended by Kocher with the convexity over the sternal notch. Kocher recommends the latter because it allows easy access to the median line, where after separation of the muscles which lie upon the trachea the thyroid lobe can be readily reached. This avoids cutting any of the muscles of the neck. The scar is low and not readily seen. Personally, I prefer the incision anterior to the muscle edge. The length need never be more than 4 inches, and it allows the least bloody handling of the gland. The one objection to the incision is that it necessitates the cutting of

some fibers of the sternothyroid or the sternohyoid. This is inconsequential, for the fibers of these muscles run nearly enough parallel to allow of separation directly through their bellies, and only a few fibers of the one or the other have to be cut at the ends of the incision. This opens the field perfectly for the largest goitre I have had to deal with. The scar is small and located in an anatomic position which to some extent renders it less apparent.

There are some precautions to be mentioned. The capsule of the gland is usually adherent to it, thickened and very vascular. In separating it from the enclosed gland a very considerable amount of hemorrhage follows. This is avoided to a certain extent by ligating the superior thyroid artery first. Just under the muscles, coming from above and entering the top of the gland, this vessel is easily found. It frequently enters as several branches, and care must be exercised to ligate all of these if the main trunk can not be gotten at. The next difficult step is securing the inferior thyroid artery. This can only be done after raising the gland from its bed and carrying it toward the median line. The whole vascular apparatus is so friable that it is possible that some vessels of size be torn in this separation and bleeding hard to control. To render this less difficult, bring about very careful, gradual luxation, catching each bleeding point with a forcep as it occurs. After reaching and ligating the inferior thyroid all forceps can be removed, as these two vesesls supply the area with blood. It is wise to ligate the large veins, however, for, though forcipressure suffices to check their bleeding for the time, their lumens are apt to open later and allow of a large clot formation in the wound. A very difficult point in the operation is catching hold of the highly vascular gland with any instrument with which to hold it. Vulcella forceps tear out and cause very serious hemorrhage. I find it expedient after exposing the anterior surface of the gland, to pass heavy mattress stitches of silk from side to side, and when these are tied the forceps catch better, and bleeding does not follow any little glandular laceration. Great care must be used in avoiding the recurrent laryngeal nerve, while dealing with the inferior thyroid.

This operation should always be performed under local anesthesia. Kocher recommends a 1 per cent. solution along the line of skin incision. I prefer a 0.125 per cent. solution. It is incorrectly stated that there is no pain after reaching the deep structures of the neck. These patients, very nervous and strung to a high pitch by the thoughts of the operation, do complain of pain in handling the deep structures, and are more readily controlled when the whole area is infiltrated. Eucain, being non-toxic when used in reasonable amounts, can be freely injected in very dilute solution. Infiltration is made between the gland and its capsule just ahead of the separation. I have never required more than ½ gr. of the drug to complete the entire operation. It is wise to reinfiltrate the skin before attempting to stitch the wound. All ligatures are made with a fine silk. I have not drained my cases. At one time there was a fear that the secretion expressed during the operation into the wound, and that formed and given off from the cut surface afterward were dangerously toxic. Drainage allowed these to escape, and therefore was recommended. There is some danger from the bleeding into the closed wound afterward, this causing suppuration and septic symptoms. A twelve to twenty-four hour drain is allowable when there is likelihood of much oozing.

Socin proposed the excision of enlarged nodes. This is not to be recommended, as it is incompetent and bloody, and many thyroids are uniformly degenerated. The Mikulicz operation, proposed for the ordinary parenchymatous goitre, has been resorted to in some cases of exophthalmic goitre with double enlargement. This operation consists in exsecting a portion of each lobe. This is too bloody to be recommended. A ligation of both superior thyroid arteries and a later removal of one lobe will accomplish more, and is more readily performed.

Jaboulay's operation of exothyreopexy is not to be recommended. The process of healing is too tardy, and the benefit not as assured as by either the ligation of the vessels or the partial removal of the gland. I do not know that this method is being adopted by any other than Jaboulay.

Lastly, I shall mention the operations on the sympathetics. Surgery of the cervical sympathetics had its initiative with Alexander, of Edinburgh, who resected the superior ganglion on both sides for epilepsy. This was in 1889. Jonesco, in Aug., 1896, resected the superior and middle cervical ganglia for Graves' disease, and the operation has since borne his name. A Russian surgeon by the name of Barocz proposed the operation as early as 1893. In my one case for exophthalmic goitre the operation was done in two sittings. The incision being made along the posterior border of the sternocleidomastoid. It can be readily done under eucain anesthesia.

Whatever the operation performed, general anesthesia should not be used. The myopathy and the vaso motor disturbance makes it exceedingly dangerous. This caution against general anesthetics holds also where the operation is for some other purpose than to relieve the symptoms of the exophthalmic goitre. Strange to say, the condition which follows operation upon these cases under general anesthesia is alike, whether done for the relief of the goitre or for other purposes, indicating that handling of the gland is not an explanation for it. I recall a case in which I used general anesthesia in the curettement of a bleeding uterus, following an abortion, in which all other means had failed. For two days following the operation the pulse rate was between 190 and 210. Eventually, she recovered from the immediate danger, only to succumb to an enteric attack later.

An objection to the use of cocain based upon the report of Riviere and Edmunds is not well taken; they assert the symptoms of cocain intoxication correspond to those of Graves' disease. Even if so, I can not agree with those who consider a unity of action in the two cases. However, in using eucain anesthesia, the amount of the drug is too small to produce additional intoxication.

The results from operative treatment of Graves' disease have been, on the whole, gratifying. Naturally, they vary somewhat with different operators, and also with the character of operation. Mortality has been surprisingly low; in 1896 Starr gave a record of 190 cases collected, with a mortality of only 12 per cent. Kinnicut the same year presented the record of 187 cases with 7 per cent. mortality. Schulz records 20 cases without mortality. The most valuable record of the present time comes from Kocher, of Berne, in which he had four deaths in 59 cases operated upon by himself. In these, the operation could not be held entirely responsible. Ligation had in the past a larger per cent. of mortality than thyroidectomy, but there should be no reason for this at the present time. In the group of cases

I present, the one death was undoubtedly the result of having given a general anesthetic.

The relief of the symptoms of Graves' disease has been gratifying. A fair average for the cures from operative procedures during the last ten years may be stated as 60 per cent.; of decided benefit 15 per cent.; and of deaths and failures, the remaining. In the 7 cases surviving the partial thyroidectomy performed by myself, the symptoms in all practically disappeared. Betterment was noted in all but one within forty-eight hours. The continuation of a high pulse in Mrs. W. was due to the pulmonary complication. Nervousness in each case disappeared almost completely before leaving the hospital, with the exception of the last case operated on but a few days since.

In one of my cases the nerve was injured by being grasped by forceps, and though the ligature was put about the vessel afterward, in such a manner as to avoid including the nerve, the voice was never quite normal afterward. Two of the cases had a slight tetanic convulsion immediately following the operation, but recovered as speedily as the others, without apparent ill effects. Mrs. B. had an interesting condition in that the right lobe of the thyroid was the larger, while the left eye was most protuberant. Exophthalmia in her case disappeared entirely after operation. Case S. S. carried her child to full term under a far more comfortable condition than was possible without relief of the exophthalmic goitre symptoms. After the operation certain symptoms may continue for a longer or shorter time before disappearing. The most persistent of these is the exophthalmia. In my cases ocular co-ordination was one of the first noticeable benefits. The physchic disturbances which follow, I believe, may be attributed to an infection of the wound in the majority of cases. This is illustrated by my last case. Three days after the operation she sat up, declaring herself better than for sometime. Her pulse and nervous symptoms certainly indicated this. On the sixth day she began to complain of pain in the area of the wound, which was the result of a slight inflammatory reaction. After that she became extremely irritable, taking marked dislike for her nurse. In her case the whole of the left thyroid was removed, with the exception of a small portion of the upper end, containing an apparently normal para-thyroid.

The question arises did the presence of the para-thyroid produce this excitation, or was it septic? The removal of the para-thyroids in animals gives rise to symptoms like those of Graves' disease, but I am at a loss in the absence of the thyroid proper to account for the presence of these bodies producing any such effect.

The character of the gland changes differed in the various cases. Vascular degeneration was apparent in all, but in many there were primary conditions not related to the exophthalmic goitre, and in some, undoubtedly secondary changes, consequent upon the marked vascularity of the thyroid.

As time will not permit a discussion of these differences in detail, I shall have to present them in a later paper.

DISCUSSION.

Dr. W. W. Grant, Denver—I have had no experience, whatever, with the operation for the treatment of exophthalmic goiter. The operation is more particularly appropriate to certain cases of traumatic epilepsy and glaucoma. Kocher, in 200 or 300 operations performed during the last two or three years, has used a solution of cocain. He has abandoned the use of general anesthetics, because of the unsatisfactory results, one of which is vomiting, which may occur during the progress of the operation, and if any surgeon attempts to perform this operation on a reasonablly large tumor, and particularly on a vascular one, without due consideration of the difficulties and complications that may arise, he is liable to a rude awakening. I have performed only a few of these operations, but I invariably open the capsule. It is much easier to make the incision through the skin, dissect from the tumor, and then open the capsule. It is much easier to ligate the arteries, and the operation can be done much more quickly; and this is an operation demanding all possible celerity. I had a case two or three months ago, the largest of these tumors that I have ever removed. It occurred in a woman 40 years of age, and the tumor had existed for twenty years. Whether or not we can explain it, it is a fact that the condition of many of these patients, although seemingly good, is not so in reality. They have but little resisting power. They succumb to the slightest hemorrhage as well as to anesthetics, their condition becomes alarming at times during the most critical period of the operation. After opening the capsule I had no difficulty in ligating the inferior thyroid vessels, but in separating the tissues for the superior thyroid I opened a sinus with the finger and a blood stream came out, which, it seemed, was as large as the little finger. It was quickly arrested, and although but a small amount of blood was lost, it was noticed that the patient was in a state of collapse. I proceeded with the operation, while assistants used restoratives and the patient recovered quickly, and her convalescence was uneventful. I always prepare the patient for such an operation. I insist that the patient should remain in the hospital for three or four days (or a week or more) and use 1/30 of a grain of strychnia three or four times a day. I have found this to be very useful. If necessary, atropin may be administered before the operation as a heart tonic. I have found it very appropriate in these cases. The amount of cocain which Kocher uses is a 1 to 2 per cent. solution, but I have not employed it because I fear its effect on the heart, especially in large tumors. I have used chloroform, but fear general anethesia also.

Dr. Emmet Rixford, San Francisco—Goiter is a disease which produces fearful suffering to the patient, and whether we can cure those patients by operation or not, we are doing a tremenduous service to them, if we can alleviate their symptoms. But the operative treatment is not so simple as it may appear. The problem is an extremely difficult one. Exophthalmic goiter may be said to be of two sorts, primary exophthalmic goiter and secondary exophthalmic goiter. By the latter I mean those cases in which the disease or symptoms supervene in the presence of existing goiter, and prognosis from operative procedure is infinitely better in the latter class of cases. In these cases there is very often an encysted thyroid adenoma, which is the seat of the goiter. The operation is much simpler in those than in the so-called primary exophthalmic goiter. It simply requires the removing of the adenoma, if the capsule can be identified. The operation should be undertaken with the greatest caution in those cases in which the heart shows degeneration. Confidence is of the greatest value to such a patient, and he should be made to rest and become accustomed to the surroundings in the hospital, mental as well as physical preparation for the ordeal being necessary. The greatest danger, as Kocher has definitely demonstrated, is the anesthetic. I have seen the greatest trouble from an anesthetic, the heart beating faster and faster until it reached 200, then 300 per minute, and finally became too fast to be counted. These patients perspire tremendously. They do not stand antiseptics well, and they should be used with the greatest caution. They do not stand sepsis well and, therefore, the greatest care should be used to have a perfect technic. I have operated on four cases of exophthalmic goiter, protecting the wound by a piece of sterilized cloth around the neck, and held up by uprights at the end of the table, so that the patient cannot see the hemorrhage, and so that he could not see what was going on. The sight of the forceps and instruments, etc., increases the nervousness of the patient. I employ 1 per cent. cocain as a local anesthetic. I prefer to make the transverse incision where the tumor is not very large, principally because of

the cosmetic effects. Women are much more likely to have this condition than men, and the transverse incision can be made very low down and the scar can always be covered by a bit of ribbon. The vertical scar always sticks up above the collar. The incision along the sternocleidomastoid always gives more room and where the tumor is large, it is the preferable operation. I was interested in hearing Dr. Witherspoon speak of opening the posterior fascia of the neck and enucleating the tumor. Kocher speaks of cocain being of assistance. In my last case that I operated on I thought that it was so simple that I could remove it without much of a wound. I did not draw the gland to the middle line, but worked from the outside. I passed the ligature around some vessels and the man indicated that he could talk. The ligature was removed and the man has since recovered his voice. As to the relief of these exophthalmic symptoms, in certain cases, it is wonderful and often immediate. I had one case that had been having from fifteen to twenty passages from the bowels a day. She suffered from profuse perspiration, the sheets had to be changed several times during the night. The patient did not expect to recover; in fact, she preferred to die. Within a week from the time of the removal of the thyroid adenoma she had lost thirty pounds in weight. She had been practically bedridden and unable to walk more than half a block before the operation, but within three months thereafter she had ridden a bicycle twenty miles over a rough country road.

DR. J. SHELTON HORSLEY, El Paso, Texas—I think we can not determine the proper surgical treatment of this condition until its pathology has been more definitely settled. There are two theories; one is that the disease is due to morbid impulses originating in the medulla and sent out over the sympathetic nervous system, the excess of thyroid secretion being due solely to these impulses. The other theory is, that the disease is caused by an excess of thyroid secretion in the blood, which acts on the nervous system. We know that in cases of exophthalmic goiter there is nearly always present an excess of thyroid secretion. However, this is not universally true, for some French surgeons have observed this disease in cases in which the thyroid gland had been previously removed by operation and in cases in which it was apparently congenitally absent, or at least so small as to escape detection. These facts have been very well brought out by Dr. Alfred Gordon, of Philadelphia, in a paper in the *Philadelphia Medical Journal* a few years ago. If this first theory is correct, Jonnesco's operation is unquestionably the correct procedure, as it permanently interrupts these impulses by taking out all of the cervical sympathetic ganglia. If, however, the second theory is correct, Jonnesco's operation is clearly inapplicable, and the only logical procedure is excision of the thyroid gland. As these two operations are founded on pathologic theories that are diametrically opposed to each other, it does not seem proper to use indiscriminately either the Jonnesco operation or excision of the thyroid, depending on whichever may be easier performed in a given case.

About three years ago I operated on a case of exophthalmic goiter having all the classical signs and symptoms of that disease. I did a partial Jonnesco operation, removing the cervical sympathetic ganglia on the right side of the neck. I intended removing them on the left side also, but the patient's condition forbade it, as her pulse was about 200 when the right side was finished. The operation was reported in the *Annals of Surgery* about eight months later, as it was one of the first cases in which the Jonnesco operation for exophthalmic goiter had been done in America. At the time of the report, she had improved wonderfully; pulse was 100 and she had gained in weight more than 30 pounds. The swelling in the thyroid, however, had not perceptibly decreased. Soon after this time, the patient began to get worse, and is now in the same condition she was in when first operated on. A second operation for removal of the ganglia on the left side of the neck, though proposed, has been rejected. It seems that cases of exophthalmic goiter may be cured, or at least relieved and improved, by either Jonnesco's operation or excision of the thyroid—operations which are founded on entirely different pathologic theories. It has occurred to me, in view of the improvement and subsequent relapse of my case and after reading the literature on the subject, that operation may have the same effect in exophthalmic goiter that is attributed to trephining in epilepsy. In other words, any operative procedure that is sufficiently severe to affect profoundly the nervous system, may result in relief of this disease, just as epilepsy is often apparently cured by simply trephining.

DR. T. C. WITHERSPOON, St. Louis—In regard to the indication for operation in exophthalmic goiter I believe that these cases should first be subjected to internal medication and then, if that fails, we should operate. In regard to the last Jonnesco operation I am not in a position to express an opinion on it. I was not gratified by the results obtained in these cases. I have not done it in exophthalmic goiter but once, but I have tried it three times in epilepsy and in none of the three cases did I secure results that were very gratifying. The one important thing that I want to speak of is the giving of a general anesthetic to these patients. We should not forget that when they are operated on for removal of the thyroid or for any surgical condition whatever they suffer tremendously from the effects of a general anesthetic. I remember a case I had in which the pulse was from 140 to 150, and I gave chloroform to allow of uterine curettement, and her pulse ran up to between 190 and 220, but she ultimately recovered from this condition. A general anesthetic is dangerous, and those who operate under general anesthesia are going to obtain poor results. In the next place those gentlemen who prefer simply to deal with the gland by primarily shelling it out I think are going to regret it some day. You should tie the blood-vessels early. There is but one way to tie them, and that is to get back of the fascia. If you get back of the fascia above the gland and run your finger behind the gland you can separate the carotid sheath and vessels from the gland, and render ligation and separation of the structures easy. I had one case in which a portion of the gland had grown down back of the sternum and another in which the gland was very deep in the neck, so that they are very different in shape and can not be dealt with alike.

PATHOLOGY AND TREATMENT OF SMALLPOX.

AN ANALYSIS OF OVER TWO THOUSAND CASES AND OF FIFTY AUTOPSIES.*

NELSON D. BRAYTON, A.M., M.D.

Assistant to the Chair of Dermatology, Syphilology and Clinical Medicine and Demonstrator of Bacteriology in the Medical College of Indiana.

INDIANAPOLIS.

CLASSIFICATION.

It is not my intention to discuss in detail the problem of the pathology of smallpox, but only to utilize in so far as practical the knowledge acquired by personal observation and autopsy in the treatment of this disease. The subject of the pathology of smallpox is in itself one of large scope and bearing, and worthy of single effort. Inasmuch as the tendency of medicine at the present day is to build the treatment of disease on the knowledge acquired of anatomic defects, it seems consistent to group the two headings.

The pathology of smallpox comprises at least three distinct considerations: First, the conditions arising from the poisonous influences of the variolous contagion itself (mainly purely speculative and relating to black smallpox). Second, the conditions arising from the maturation stage; and third, the incidental complications and sequelæ. In the latter class are considered boils, abscesses, phlegmonous conditions, erysipelas, the eye symptoms and the accidents to pregnancy.

* Presented at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, W. L. Baum and J. A. Fordyce.

While it may be impossible in many instances to draw any line of demarcation between any or all of these conditions, it is well to have some basis of division, in order to more perfectly understand the clinical feature or features of the disease. Likewise, different varieties of the disease must be recognized and classified. I have unhesitatingly adopted the classification of Osler as the best and most perfect I have yet seen. His five distinct varieties of the disease are arranged as follows, and now form the generally recognized classification:

Variola Hemorrhagica.
- (*a*) Purpura variolosa; "black smallpox."
- (*b*) Variola hemorrhagica pustulosa.

Variola vera.
- (*c*) Variola confluens.
- (*d*) Variola discreta.
- (*e*) Varioloid.

THE PATHOLOGY OF PURPURA VARIOLOSA.

But little is known of this condition, the rarest of all forms of smallpox, and in itself essentially and always fatal. The awfulness of the disease impresses itself on the physician and beholder. It is distinctive from its fellow forms in that the patient dies always before the appearance of an eruption. Those who have been fortunate enough to examine these cases postmortem report abundant blood extravasations into the serous membranes and loose connective tissue of the body; into the muscles, the joints and bone-marrow. These, in conjunction with the well-known external manifestations, namely, petechiæ of the skin of the abdomen, chest and crural region and flexures of the arm, and conjunctival ecchymoses, are the main pathologic conditions.

In the one case in which I have had the privilege of an interior examination, blood was found in the vitreous humor of the eye in profuse quantity. This is the one and only condition which I am able to add to the literature of variola purpura, and which I have so far failed to find in any text-book or book of reference on the subject.

Blood examinations have been made by various observers, including the writer. So far, nothing pathologic has been determined. The blood is thin and dark, and clots very slowly. No change was noticed in the size or shape of the blood corpuscles.

The main lesion in purpura variolosa seems to be a tendency to blood extravasation, either into interstitial tissue or in or through the mucous membranes. Whether or not its etiology is that of "blood dissolution" of acute infectious diseases or of the "bacterial coagulation thrombosis" of Unna is as yet unproven. A condition of acute hematophilia exists—severe in its intensity—and its obscure etiology and exact pathology is as yet a matter of pure speculation.

Mode of Death.—Death occurs certainly from the intensity of the variolous contagion, before the appearance of an eruption, and the intellect is unclouded to the end.

VARIOLA PUSTULOSA HEMORRHAGICA.

This variety of smallpox distinguishes itself from purpura variolosa in that an eruption always develops to a greater or lesser degree. Elevation of a macule to the papule always occurs. Hemorrhage may occur into the lesion at any time in the cycle of its existence. I have seen it occur in the macule, the papule, the vesicle and the pustule. Hemorrhage may occur into the conjunctiva and bleeding occur as in purpura variolosa from the nose, mouth, arms or vagina.

Internal lesions present themselves always in the respiratory tract. These are always the cause of much distress and discomfort to the patient, and undoubtedly have much to do with the unfavorable prognosis of this division.

In contradistinction to purpura variolosa the lesions of variola hemorrhagica pustulosa appear with perfect regularity on the mucous membranes as above described. On account of the varying conditions governing the secretion, digestion and motility they never go to full development, and present themselves as small ulcers with a surrounding inflammatory base. These undergo a retrograde metamorphosis, break down and discharge a thick purulent secretion which is coughed up by the individual in the form of a thick, ropy mucus. They often heal and leave no cicatrix or evidence of former inflammation.

I have repeatedly demonstrated these lesions at autopsy, even in the smaller bronchioles.

The differential feature, then, of variola hemorrhagica pustulosa is an eruption with hemorrhage into the lesion of eruption, and not the simple interstitial or subcutaneous hemorrhage, as exists in purpura variolosa.

Mode of Death.—The intensity of the poisonous element of the contagion of variola may cause death with the early hemorrhage into the macule as early as the fourth day, or the individual may go on with subsequent affliction and perish later of complication or sequelæ. Again, he may recover. In any event, this condition is very grave, and the pathologic conditions are many.

VARIOLA CONFLUENS.

Variola confluens presents the classical clinical picture of smallpox. It is the true type of the disease. Feeling better on the fourth or fifth day of an often undiagnosed illness, the patient may notice a small macule or a small round spot on the brow or wrist. On the next day, fifth or sixth, appear many more bright red spots, with a tendency to grow hard as the day advances. These papules or pimples undergo the successive changes of vesicle and pustule. On the eighth, ninth or tenth day they may run together, producing great blebs, and the individual falls into a condition of profound septicemia from absorption of poisonous toxins elaborated in the countless pustules. Co-incidentally bacteria develop in the blood and the patient dies from profound sepsis, and often in delirium.

Extensive pharyngeal, laryngeal, nasal and bronchial lesions are always present in severe cases of variola confluens. They are often confluent, and the writer has demonstrated at autopsy lesions almost co-extensive in length with that of the trachea itself. These internal ulcers again add to the severity and distress of the patient's condition, and are a frequent cause of pulmonary complication. The author has seen frequent deaths occur as the result of these often overlooked, untreated and unknown conditions of the respiratory tracts, and believes that too much emphasis can not be placed on the consequent necessity for proper therapeusis for these untoward conditions.

Pericarditis, pneumonia, pleurisy, albuminuria, if arising during the course of the disease, present their usual manifestations, and need not be considered in detail.

Of special symptoms, those which concern the eye are of prime importance. In former times one-half the cases of blindness were due to smallpox. In recent years, thanks to vaccination, this percentage has very materially decreased. The eye symptoms may be either extrinsic or intrinsic.

1. Symptoms in which the external parts of the eye are the seat of pustules or pocks, namely, the lids and marginal conjunctiva.

2. Where the eye or eyeball is itself involved. *a*, conjunctiva; *b*, cornea; *c*, interior of eye. The pocks or pustules appearing on the eyelid in no way differ from those of other regions, and except for their inconvenience are of no importance. Those which appear on the conjunctiva, if not adjacent to the cornea, are likewise of little import.

Those which appear on the cornea, however, have a distinct pathology, and their clinical history is often a matter of deep concern to the practitioner. Corneal ulcers appear most frequently in albuminuric patients. Rapidity of development is the characteristic feature of a variolous corneal ulcer. The pock may entirely destroy the area of the cornea on which it is situated within twenty-four hours. In such cases blindness almost invariably results.

Panophthalmitis may occur. I had one case in which I did an enucleation. Death occurred. Albumin was present in this case, as in many of my other eye cases.[1]

VARIOLA—SEVENTH DAY.

Fig. 1.—Showing the influence of the disease modified by vaccination (indicated by cross). The black spot on the arm is a taking vaccination. Below, at the elbow, is a small confluent patch. Notice the dissemination of the lesions and their limited number. From the author's wards, at North Brother's Island, New York. This child was one of a ward of children removed from the New York Foundling Hospital. The original infecting child perished. Vaccination was immediately practiced and the disease was mild in all the cases.

THE HISTOPATHOLOGY OF THE SMALLPOX LESION.

It is to Unna of Hamburg that we owe any knowledge of the histology of the smallpox lesion whatsoever. His view is that the stratum mucosum softens and becomes edematous in its upper layers. An exudate appears; suppuration occurs from secondary infection, and owing to the fibrinous material exuded from the cells, septa are formed. The exact cause of the umbilication, however, is unknown.

Following the removal of the scab a depression in the skin presents itself. Depending on the ability or rapidity of epithelialization depends the character and degree of pitting. Quick epithelialization generally means an absence of marking and the converse well-known clinical fact has long been established, viz., slow pustulation is not only dangerous to the patient, but means extensive scarring as well.

The other varieties of variola present no distinct pathologic condition not already considered.

THE TREATMENT OF SMALLPOX.

The treatment of smallpox divides itself naturally into: 1. The prophylactic treatment; 2, the treatment of the disease itself; 3, that of its complications and sequelæ. Special consideration will also be given the red-light treatment.

SYNOPSIS.

1. PROPHYLACTIC TREATMENT.
   (*a*) Isolation and disinfection.
   (*b*) Vaccination.
2. TREATMENT OF THE DISEASE ITSELF.
   (*a*) Prodromal symptoms.
   (*b*) Local treatment. Treatment with baths. Removal of pustules and opening of them to remove contents—emollient treatment—prevention of scarring and pitting.
   (*c*) Constitutional treatment; purely symptomatic and supportive, alcohol and strychnia. Ammonium compounds for throat complications. Opium for hemorrhage, and intravenous infusions for the septic and hydremic stages.
3. COMPLICATIONS AND SEQUELAE.
   Boils, abscesses, phlegmonous conditions, erysipelas, albuminuria, eye complications, edema glotidis, pulmonary and vasculo-cardiac complications. Nervous symptoms and lesions.
4. THE RED LIGHT TREATMENT.
   A failure. Results observed in over 300 cases in New York and Indianapolis.

PROPHYLAXIS.

The prophylactic treatment will be dismissed with but a few words. In company with every other scientific mind, the writer regards vaccination and repeated vaccination as the only means of protection against the disease. I have no patience with those misguided health officers who advocate isolation and disinfection as the proper means of prevention. The city of Cleveland, Ohio, is a monument to such a fallacy. It is interesting to note that the health officers of that city who pinned their faith to formaldehyd have since retracted. The city of New York is a monument to the results which may be obtained by universal vaccination. Eight hundred thousand vaccinations in one year at public expense have abolished the disease in that city, as it will in every well-vaccinated locality.

Recent vaccination absolutely prevents smallpox. It has afforded me my only protection. During the last four years I have been mixed with every variety of smallpox, from purpura variolosa to the mildest varioloid. I have never had smallpox, and my one safeguard has been repeated vaccination. During these four years I have been vaccinated at least fifty times, two of these vaccinations being successful. Vaccination provides immunity for varying periods of time from two to thirty years or more. Neither painful nor dangerous, and applicable at all ages, from the newborn babe to those of mature years, it should be insisted on whenever smallpox is epidemic. However seemingly perfect isolation or detention may appear, whenever smallpox is prevalent they will show themselves to be defective means of prevention.

Truly, indeed, may it be said that as regards smallpox the struggle for existence is the struggle of the vaccinated. And just as truthful is the converse proposition that the survival of the fittest is the survival of the vaccinated, in which the unvaccinated perish.

THE TREATMENT OF THE DISEASE ITSELF.

Purpura Variolosa.—No observer of smallpox has as yet published a case of the survival of a patient once

1. I can not agree with the authorities in the 5th volume of the XX Century Practice of Medicine on the rarity of eye symptoms. Such statements as are made by Homer and Swanzey are certainly far from giving a correct opinion of these complications.

diagnosed as suffering from black smallpox. Awful and tragic to behold, with the knowledge back of the physician that every other case of this variety has perished, and that this one can be no exception, he may for the first time realize the horror of this disease. The intellect is generally keen to the last, and if the patient be apprised of his condition he may even give directions as regards his business affairs or to his family, even to the moment of his death.

Pain in the back is one of the most prominent symptoms of this variety. It is relieved only by morphin, generally given hypodermatically. Large dosage should be employed.

The only theoretical treatment that might seem to be of service in this condition would be abstraction of the blood in large quantity and the intravenous infusion of saline solution. In the only case in which I had an opportunity to try this form of therapy the patient died

VARIOLA—NINTH DAY.

Fig. 2.—Showing hand and arm of woman at the ninth day of disease. Notice the swelling of hand and wrist; the inflammatory zone around the vesicles; the tension in some, and the umbilication in most vesicles, and their depressed centers. Just at the lower end of the ulna is a confluent patch made up of four previously separate vesicles. From the author's cases at North Brother's Island, New York. Photographed by Dr. S. Pollitzer.

before the necessary measures could be provided for even this simple procedure.

Variola Pustulosa Hemorrhagica and Variola Confluens and Discreta.—Prodromal symptoms may be treated in the usual manner. The use of opiates and laxatives with baths for the fever and delirium is to be encouraged.

In case of marked epistaxis, or hemorrhage from the mouth, anus or vagina in the hemorrhagic type of the disease, recourse should be had to large doses of opium. Tincture of opium or powdered opium should be given unstintedly. The author has never seen good results follow the use of the various salts of iron. Unpleasant and nasty to take, they cause the patient much uneasiness and distress. They can not substitute the somniferous effect derived from opium. Opium should be exhibited unsparingly and unhesitatingly in large doses in hemorrhagic smallpox.

External Treatment.—As soon as the eruption appears the patient should at once be given hot baths. If no tub can be provided hot packs should be substituted. These should be given at intervals of every three or four hours and continued as long as they do not enervate the patient. The hot bath promotes diaphoresis and kidney action; helps eliminate poisonous elements in the blood and has a quieting influence on the nervous condition of the patient. A sense of relief and comfort is also furnished that can not be obtained by any other means.

After the pustules have fully formed and in case resolution does not immediately occur, the pustules should either be removed or their contents evacuated. For this purpose, in cases of slow pustulation and with little tendency to resolution, the writer has frequently used a sharp spoon or curette and simply curetted away great masses of pustules. In this way many foci of suppuration are removed and the general tendency of the suppurative stage to an unfortunate issue averted.

After the removal of the pustules the patient may be given an antiseptic bath of either carbolic acid, bichlorid of mercury or boric acid. On account of the mechanical inability of any antiseptic solution to penetrate through the fibrinous exudates which compose the outer crust or walls of the individual pustules, I have no confidence or faith whatsoever in the so-called antiseptic bath treatment. My experience has proved its inutility and utter uselessness, and the mechanical features which I have already described are against even its theoretical employment.

Antiseptic baths in the treatment of smallpox to be of any service should only be given after the pustule has been incised or removed. The emollient treatment, which may be employed during the period between the baths, may consist of such simple remedies as a mild carbolic vaselin and the use of a mild dusting powder, such as boric acid.

The Prevention of Scarring or Pitting.—To a great extent this is entirely outside and beyond the power of the physician to either avoid or modify. Whatever remedies are of service in this regard must be those which possess the power of keratolization. Chief among these is the well-known salicylic acid. In 3 or 4 per cent. ointment form it causes increased epithelialization. Applied immediately after the pustule is dry enough to remove, it may, by its keratolytic action, cause enough epithelium to grow to quickly fill the pit and also stimulate the subcutaneous tissue beneath. I believe I have seen some benefit follow its use, but in well-marked cases of confluent smallpox but little can be accomplished.

Of other procedures that have been advocated, such as the use of silver nitrate stick in the pustule itself, iodin, tannic acid, etc., they are only mentioned to be condemned. Salicylic acid does all that is claimed for them and much more.

Continuous application of hot cloths to the face and protection from the air either by oils or salves during the pustular stage is also to be recommended. As soon as large scales or crusts form they should be removed and some antiseptic medication applied, followed by the use of an ointment.

The Constitutional Treatment.—The constitutional

treatment of smallpox is purely symptomatic. Control of fever and delirium by baths, of hemorrhage by opium in large doses, supportive measures for the heart, such as alcohol, strychnia and digitalis, especially in the septic stage. The diet should be liquid, mainly milk and egg-nog, broths and soups. Water should be administered *ad libitum*, and the patient forced to drink copiously.

Of special symptoms to be met and receive appropriate treatment the pulmonary tract must be given special attention. It often happens that the mucous membrane of the respiratory tract may be almost entirely denuded from the teeth and nose to the finer bronchioles. We have many reasons to believe that this condition may obtain, and yet the patient may entirely recover.

In my collection of tracheæ which I have removed at autopsy I have one which shows lesions as above described, and in which the ulcers are at least four inches in length. Yet patients with known lesions of this character do recover.

It is therefore essential that something be done for this conditon. I have secured the greatest benefit to my patients through the use of ammonium chlorid and aromatic spirits of ammonia exhibited in full doses. Liquefaction of the mucus and loosening of the chest occurs, and the pulmonary action may be carried on unhindered.

The Hydremic State of the Blood.—There is but little doubt that in the full pustular stage of smallpox with co-existent sepsis, delirium and coma there exists a markedly hydremic state of the blood. Not only this, but the blood carries in solution an immense number of toxins.

To combat this condition is one of the greatest problems in the treatment of the maturation stage of smallpox. In my wards at North Brothers' Island rectal enemata-enteroclysis was often resorted to. On account of the difficulty of making the patient retain these enemata but little benefit was derived from their use.

In order to better combat this condition I have proposed and used what I consider a far better method, namely, direct intravenous infusion of normal saline solutions. Their action is to dilute the blood of known poisons (toxins or ptomains absorbed or manufactured from the pustules of smallpox) and to stimulate the heart in a period of depression owing to a decreased blood volume, and to promote excretion.

I have found marked benefit to follow their use, and believe the knowledge now given of their use is a distinct and valuable acquisition to the literature on the therapy of smallpox.

COMPLICATIONS AND SEQUELÆ.

The boils and abscesses which so frequently follow in the desiccating stage should be widely opened by free incision. Free drainage should always be secured. If deep cellulitis occurs the part should receive appropriate wet dressings and the knife be freely used. If albuminuria occurs it should receive appropriate treatment with hot packs and the diuretics; special care should be observed in regard to the eyes if albumin is once detected, and they should receive frequent inspection.

Laryngitis is a serious complication in many ways. It may cause necrosis of the larynx or cellulitis of the surrounding parts with quick edema following and death supervening. In three of the author's cases at North Brothers' Island intubation was practiced for this condition. In two of these cases it was afterward necessary to resort to tracheotomy. This quick and sudden edema is a serious affection, and its possibility must always be considered when aphonia is present in the patient.

The eye symptoms should receive appropriate treatment. Corneal ulcers should be early detected, cauterized with the silver stick direct, and then receive frequent irrigations with a mild antiseptic solution such as a saturated solution of boric acid.

Pneumonia and pleurisy are dangerous complications, and most often fatal. Pneumonia, when it occurs, is often a septic bronchopneumonia, and the pleurisy a purulent effusion. Naturally, but little can be done in such conditions. Cardiac complications are rare. The writer has seen but very few in the cases under his observation.

Diphtheria in children is a common affliction. It comes on suddenly owing to the soil already prepared for it by serious and numerous throat and nasal lesions. Antitoxin should necessarily be exhibited in large doses, and an early diagnosis is imperative.

Nervous Symptoms.—Delirium is one of the most marked characteristics of the disease. It occurs early, and is much more severe than that often met in typhoid fever. Delirium tremens is often seen in men addicted to alcohol, and is a most unfortunate complication. The general run of somniferous and nervous depressants are often powerless to control the agitation of the patient, and simple restraint is the only means of service. If too wild or flighty the patient should be put in a strait-jacket and kept in restraint as long as indicated.

VARIOLA—ELEVENTH DAY.

Fig. 3.—Showing invasion of soles of feet at eleventh day of disease. From the author's cases at North Brother's Island, New York. Photographed by Dr. S. Pollitzer.

I have seen but two cases of insanity follow or occur in or during the course of variola. One of these was permanent.

THE RED-LIGHT TREATMENT OF SMALLPOX.

In the May 2, 1903, number of THE JOURNAL of the American Medical Association there appears an excellent analysis of the claims of the efficiency of red light in the treatment of smallpox by Dr. J. F. Schamberg. This excellent exposition of the subject by such an eminent writer is worthy of reproduction in even the popular press. Dr. Schamberg takes up in detail the history of the red-light method and shows its fallacies when applied to the treatment of variolous subjects. To all of what Dr. Schamberg says I heartily agree. Dr. Finsen was not the originator of the red-light treatment of smallpox.

John of Gaddesden, six centuries before, had used it in the treatment of an English prince, and numerous instances of its use have been recorded since. In the detention hospital at North Brothers' Island two wards were fitted up in an appropriate manner to try this form of treatment. In the Indianapolis City Hospital Detention House two wards were also fitted up to try the red-light theory.

In both of these hospitals I have had abundant opportunity to watch the effect of elaborate arrangements to try the theory of red-light treatment of the disease. With the experience of at least 300 cases I regret that I also must corroborate the results that Dr. Welch and Dr. Schamberg arrived at in Philadelphia in the two cases in which they tried the red-light treatment of the disease, and say that there is nothing in it. While it may sound well in theory, and look beautiful in practice, yet it is nevertheless true that the dead are still removed and the pitted and the scarred still recover in a red-light hospital.

In the Indianapolis Hospital suppurative fever and death have not been less in the red-light wards than in the other wards. A careful daily investigation of the patients showed conclusively that the patients under the red-light treatment have not done any better than did an equal number of patients suffering during the epidemic in four other wards exposed to sunlight and the ordinary incandescent electric light. During the time that the red light has been in use in this hospital about thirty patients have died in the red-light wards. Those from the red-light wards were as badly pitted as those from other wards.

We may conclude that the extent of scarring, pitting or pocking depends entirely on the severity of the disease and the depth to which the pustules affect and enter the true skin.

The question of the prevention of pitting is really not within the hands of the physician. It is rather that the physician and the patient should be grateful that recovery has occurred at all than that they should feel chagrin or remorse that pitting has occurred despite their earnest but useless efforts to prevent a condition which is wholly outside their power to ameliorate, to resist or to relieve.

CLINIC AT CHARITY HOSPITAL, NEW ORLEANS.

CONDUCTED BY DR. ISADORE DYER, NEW ORLEANS.

A clinic was held at the Charity Hospital, New Orleans, May 7, as a part of the program of the Section on Cutaneous Medicine and Surgery. Several cases of leprosy and other interesting skin disorders were shown and commented on by Dr. Isadore Dyer. He remarked that he made it a special point in cases of leprosy to note the effect of the disease on the face; this he believes is characteristic.

The first patient shown was a man 32 years old, who reported at the hospital first in 1897. At that time both hands and face were covered with tubercles, which were still very evident up to a year and a half ago. At the present time he is comparatively free from tubercles, though his face is scarred where they formerly existed. He has fair use of his hands, and the only actual evidence of the disease at present is in his feet. He was born in New Orleans in the district where the old leper hospital stood. Dr. Dyer remarked that whether there was any direct connection or not he is not aware; the fact is that nearly all the cases originating in New Orleans develop from that center. The patient's father was German, his mother English, and both had lived nearly all their lives in New Orleans. This emphasizes a point he had frequently remarked, that leprosy does not occur in anyone who has lived in New Orleans less than ten years. The only exception to this of which he is aware was a Norwegian, who was sent to the clinic by the U. S. Marine-Hospital Service and returned by the same boat on which he came to the city.

The treatment in the case consisted of 1/60 of a grain of strychnin with 40 drops of chaulmoogra oil, three times a day. The patient has been taking this since last December. The general condition of the skin is improved. In spite of the fact that he has advocated other lines of treatment and experimented with antivenene serum, Dr. Dyer has fallen back on chaulmoogra oil, and is inclined to agree with Bibb of Saltillo, Mexico, who says that any person who gets enough of the oil will get well, provided he has not been mutilated. The results of the Charity Hospital are in harmony with that opinion. He has two patients on chaulmoogra oil, one taking 60 drops without trouble, and a large amount of the pigmentation has disappeared from that patient's face.

Case 2 was a woman, 41 years of age, with the same disease. At first glance the diagnosis would not be clear, as there was no evidence of disease in the face. She also was of German parentage. In the reports of cases from Louisiana at the Berlin conference it was remarked that the most frequent cases were natives of Louisiana of either French or Spanish or of mixed French and Spanish parentage. This woman was born in New Orleans, in the fourth district; not the same district where the other patient was born. She has had some spots on her hands, but most are on her legs. The color has gone in a large degree. Lepers were not isolated before 1886, and the patients in the Leper Home formerly received no medical treatment. It seems a matter of conscience that patients suffering from this disease should not be merely isolated and allowed to die. Isolation is compulsory. This patient is taking only five drops of chaulmoogra oil, as that is all she can bear. The disease in her case is of five years' duration, and it is now considerably improved. She has taken the treatment regularly, but has taken the oil only in small doses.

Dr. Hopkins has charge of the treatment of the cases at the Leper Home. Out of 40 cases treated for the last year and a half two or three are nearly ready to be discharged.

The third case exhibited was a very recent one. At first glance the color is not characteristic. There is a good deal more symmetry than is usually met and the condition looks more like erythema than like leprosy. The spots are hardly marked enough for leprosy, but are all anesthetic. Those on the leg are characteristic lesions, the center being lighter. The woman says the spots on the arms and face came first. She was born in New Orleans and lived there since 1853. She lives in the third district where the old Leper Hospital was situated. The color and thickening of the skin with the anesthesia confirms the diagnosis. This case has developed within six months. Dr. Dyer referred to an error that he made before his class. A patient came in with a lesion similar to those of the patient just seen, and Dr. Dyer made a diagnosis of erythema and dismissed the case. Two weeks later he examined the patient more thoroughly and changed the diagnosis.

Cases of the tubercular type were not shown, as they go very promptly to the home. The face is usually first attacked, and it does not require that they be sent to the clinic for diagnosis. The tubercular cases are in the majority.

Beside the leprosy cases he exhibited one of cystic epithelioma. The general condition of the patient's face is better than it has been for a long time. He has had at times as many as forty and fifty tumors existing together. Most of the spots on the body have disappeared. He has been under care for more than ten years. At first it was the custom to curette the growths, but it was found that it had to be done almost weekly, and at present resorcin is being used. The interesting thing in connection with this patient is that he had an attack of erysipelas about four years ago and the epithelioma did not disappear. In private practice Dr. Dyer is using the x-ray in these cases with good results. In this instance the patient has had the disease for about fifteen years.

Beside these cases of herpetiform dermatitis and nevus unius lateris were shown. In the latter case the Doctor remarked he had not seen the warty type of linear nevus disappear, but

the plain vesicular type he had. He has made it a rule in infants under 6 years of age not to interfere.

Another interesting case showed the effects of Unna's thiosinamin soap on a scar caused by fire. He also exhibited cases of infantile eczema which he called reflex eczema, a term for which he has fought during the last ten or twelve years. It is most common in boy children, and disappears after circumcision. If it occurs in girls regulation of the diet seems to favor its disappearance. The chief thing is to find the cause and eliminate it, then the simplest sort of treatment is effective.

Other cases of infantile syphilis, pediculosis lesions, psoriasis and chloasma in a colored person were also exhibited.

LIMITATIONS OF NON-SURGICAL TREATMENT IN ACUTE INTESTINAL OBSTRUCTION.*

JOSEPH RILUS EASTMAN, M.D.
INDIANAPOLIS.

The term "acute obstruction of the bowel," broadly used, embraces all of those conditions, however varying in their etiology and pathology, which suddenly obstruct the lumen of the intestine to the extent of interfering with the passage of its contents. It is well known that the intestine may be obstructed by omental bands, fibrous bands, the result of peritoneal adhesions, as in appendicitis or peritonitis (*ante et post operationem*), by Meckel's and other diverticula, or at the neck of an internal or external hernia; that it may become kinked or twisted as in volvulus; that one segment of the intestine may become telescoped into a neighboring segment, as in intussusception; that the lumen of the intestine may be obstructed by gallstones, enteroliths, foreign bodies or its own normal contents; that it may be narrowed by pressure of tumors from without; that its lumen may be narrowed by benign or malignant strictures, or by the pressure of neoplasms or acute swellings arising within its own walls, and by the presence of embolism or thrombosis of the arterial or venous circulation of the bowel wall. Symptoms of acute obstruction may also develop suddenly in cases of malignant, syphilitic or gonorrheal stricture.

In all of the above enumerated conditions the obstruction may be said to be purely mechanical. Cases of apparently purely functional closure of the intestine—intestinal spasm—are recorded. Heidenhain and others report a few cases of purely spastic or reflex tonic contracture. In Heidenhain's cases, the contracture seemed to be complete and irreducible. Quintard[1] collected fourteen such cases from the literature. Quintard's list is doubtless incomplete, but nevertheless cases in which complete contracture of the intestine is thus brought about by reflex irritation must be quite rare. Perhaps operation and very careful direct ocular examination in these cases would have left fewer of them recorded as of purely reflex origin. It is well known, however, that the syndrome known as ileus, as a purely reflex phenomenon, may attend or be consequent upon torsion of the pedicle of an ovarian tumor, or pinching of the spermatic cord, and that in an inorganic or functional form it may be due to ptomain poisoning or to dysentery or other inflammatory conditions in the large or small intestine. No one knows how many cases of reflex or functional interference with the procession of the intestinal contents have been included in the list of cases of mechanical intestinal obstruction cured by internal therapy.

If a surgeon, speaking from the standpoint of a limited personal experience and observation, may assume to enumerate the forms of acute obstruction of the bowel which may be cured by internal medication, the writer would include the following: First, simple coprostasis. It should be borne in mind, however, that behind the picture of simple impaction may be hidden deep strictures benign and cancerous, or compression of the colon from without by adhesion bands, etc.; second, cases of incomplete stenosis of the small intestine from chronic peritonitis. Heidenhain states that many of these cases are cured by thorough and repeated rinsing of the stomach, the use of enemata and proper dieting; third, volvulus of less than 180 dgrees when involving the colon; fourth, reflex closure of the intestinal lumen. Medical treatment of reflex ileus is not only valid, but it is our best resource. The preparations of hyoscyamus are useful agents in this form of obstruction. A single hypodermic injection of morphin may, by one brilliant stroke, efface every symptom of a violent reflex ileus, as noted by Dr. Hugo O. Pantzer of Indianapolis. It is in ileus of the reflex type alone, however, that morphin is useful, and even in cases strongly suspected of being of reflex origin, the administration of morphin or antispasmodics should not be continued too long; fifth, functional obstruction due to dysentery or other ulcerative and irritative processes, such as ptomain or lead poisoning. In such cases the cause of the ileus may usually be removed by non-surgical methods; sixth, intussusception of the colon during the early stages.

Körte has called attention to the fact that the symptoms of incarceration of gallstones are often so similar to those of a suddenly developing ileus with obstruction of the bowel, that a mistaken diagnosis of stricture or volvulus may have been made. Celiotomy is clearly indicated in such cases. Cholelithiasis is, as is well known, a surgical disease, notwithstanding it is not necessarily fatal, and is occasionally amenable to medical treatment. The ileus produced by it should be relieved by surgical removal of the cause.

No doubt in very rare cases invagination has been reduced by the forced introduction of air into the rectum, or by high colonic injections of water, but that the vast majority of these cases must be given over to the surgeon, is, or should be, well known. A volvulus of 180 degrees in the first stage of the disease may be reduced by air or water; however, in cases of volvulus reaching 250 or 300 degrees, it becomes impossible to inject water into the closed-off segment. The stenosis is complete. No one would presume to be able accurately to estimate the amount of twisting of the bowel in any given case before operation, or to specifically diagnosticate volvulus at all. As for internal stenosis due to organic stricture, it is hardly imaginable that such a case could be successfully treated by other than surgical means, and it is generally taken to be undebatably concluded that obstruction due to bands, diverticula, strangulation of herniæ and the presence of neoplasms must be dealt with surgically.

It would be obviously very difficult accurately to determine the number and character of cases spontaneously relieved or cured by non-surgical means, since after the subsidence of symptoms and cure of the patient, the abdomen not having been opened, the nature and cause of the trouble must remain in the dark. We find ourselves here on the ground of pure hypothesis. We know how difficult it is to determine the exact nature of an

1. Murphy, Prac. Med. Series, 1901.

obstructing intestinal lesion by consideration of the external signs and subjective symptoms alone.

In cases of definitely diagnosticated mechanical obstruction of the intestine of any sort, there are few surgeons who, with instruments at hand, would adopt any less radical measure than that of operation. The non-operative methods of treatment may, under very extraordinary circumstances, be used in mechanical obstruction by one who, for various reasons, feels that he dare not open the abdomen. For one, however, with proper surgical means at his disposal, to stand by with folded hands, or deal with these cases by the so-called palliative means, requires upon his part a reckless degree of indifference indeed. The palliative means are nearly always ineffectual in cases of mechanical obstruction, are often deceptive in their effects, and are never free from danger.

Even very young children stand abdominal operations remarkably well, and there is no reason why a celiotomy, if indicated, should be withheld from an infant, even if it be only a few days old. Here the methods of inflation and injection are not devoid of danger. Knaggs reports eight instances of fatal injection. In seven of these ruptures occurred. In one case, that of a young infant, only nine ounces of water were injected when a rumbling noise was heard in the abdomen, which was immediately followed by death. (Maylard.)

It will appear to any one familiar with the anatomico-pathologic nature of the condition that the reduction of intussusception of the small intestine by the injection of water or air will hardly be possible after the onset of symptoms. It is doubtful whether in the adult it is possible to force water through the ileocecal valve. In the cadaver this may be done. Here the valve may leak, but it should be remembered that this phenomenon, though it may be demonstrated by the use of force in the cadaver, can hardly be produced in the live subject.

It must be conceded that in acute intussusception, the lesion being almost always in the small intestine, little can be gained by the injection of water. Irritating enemata may stimulate peristalsis in the lower intetine, and the movements may in some degree be transmitted to the small bowel. This will hardly suffice to release the intussuscepted small intestine if sufficient time has elapsed for the establishment of a clinical diagnosis: For by this time the intussuscepted bowel will have become quite thickened and choked, or even gangrenous. The employment of massage or taxis blindly through the abdominal coverings has never accomplished anything in any case of intussusception of which the writer has any personal knowledge. The toughness of the adhesions between the layers of the intussusceptum and the sheath or intussuscipiens and the rapidity of their development are extreme.

A few cases in which symptoms of intussusception had existed for from six to nine days have been, according to reports, relieved by the combined conservative methods. The Almighty only knows how many thousands have been lost through the employment of these so-called, but miscalled, conservative methods. Operation will conserve the lives of a certain small percentage of cases of intussusception. It represents, therefore, in the strictest sense, conservative treament. Many cases of successful excision of acute intussusceptions have been reported, and in many more cases lives have been saved by the employment of the at once less brilliant and less dangerous methods of operation.

A favorable result sometimes follows irrigation of the stomach and colonic injections of water, or insufflations of air. The physician permits himself to be deceived by the comparatively good condition of the patient, and operation is postponed until the patient is moribund, then an operation is allowed and surgery is charged with a mortality.

Successful treatment of intestinal intussusception is only possible by operation performed early, while tympanites is still slight and the patient is in relatively good general condition. Later, distension of the intestine becomes so great that often, with the abdomen opened, the most careful and zealous surgeon can not find the obstruction at all.

It would be well if there were unanimity of opinion among surgeons and physicians as to the proper treatment of a malady in which the mortality is not less than 75 per cent.

Laparotomy in such a case is always a dangerous operation, but the disease unoperated is distinctively more dangerous.

Nature has shown us the way to deal with intussusception. When, as rarely happens, she effects a cure, she does it by sloughing and gangrene and discharge of the intussuscepted segment through the bowel. It may seem quite superfluous for one to declare at this day the necessity for prompt diagnosis and prompt operation in cases of intestinal obstruction of this character. But the fact is that physicians, as a rule, are not promptly making differential diagnoses in these cases, nor operating them until the patients are *in extremis* with subnormal temperature, flickering pulse and abdomens blown out as tightly as a snare drum.

Already many successful operations for intussusception in young children are recorded. Karrsberg[2] operated on a boy 3 years and 9 months old, with invaginatio ileocecalis subchronica with complete success. Bryant[3] describes a case of acute double intussusception in a girl baby of 9 months, operated on twenty-four hours after the onset, with rapid recovery. A. B. Mitchell met a case of retrograde intussusception in a boy 4 months old. It was reduced by operation thirty-six hours after the appearance of symptoms and recovery followed. Wright and Renshaw[4] reported successful operation on a 3-year-old child with invagination of the appendix into the cecum, and Eve successfully operated on an intussusception at the ileocecum in a baby. Poppert of Giessen saved an 8-months-old child with intussusception by prompt operation, and Sells[5] also operated successfully on an infant 4 months old, 18 inches of the ileum having passed through the ileocecal valve. Several dozen similar cases have been reported. Northrup, on the other hand, reports relief of a child seven months old with intussusception by high colonic injections of water, and Ouvry[6] successfully treated a case of acute colonic invagination in a male infant 9½ months old by catheterization of the invaginated bowel.

The surgeon, however, will ask, with a shrug, whether these and other similarly palliatively treated cases were really intussusceptions. Relief in Northrup's case followed free movement of the bowels and the only indications of intussusception were a sausage-shaped tumor under the liver and bloody dejections.

Fitz's statistics give fifty-one cases treated without operation, with sixteen recoveries and thirty-five deaths (69 per cent.). Pilz reported in 1870 ninety-four cases in patients under 1 year, with a mortality of 84 per cent.

2. Hospitalstidende, 1896, No. 5.

4. British Medical Journal, June 12, 1897.
5. Lancet, Aug. 31, 1901.
6. Gaz. Hebd., June 20, 1901.

From 1870 to 1891 135 cases in patients under 1 year gave a mortality of 59 per cent.[7] More recent statistics would show a much smaller percentage of mortality after operating, as the result of earlier and more skillful surgical intervention.

A case of invagination reported by Jaboulay[8] is instructive, for the reason that no operation was made, and the autopsy showed that surgery would doubtless have saved the patient's life. The case was received into the clinic forty-eight hours after the appearance of symptoms. There was no stercoraceous vomiting. On the following day there were bloody stools. Operation was withheld because it was assumed that after seventy-two hours the vitality of the intestine must be practically lost, and, moreover, the lesion could not be accurately located. Administration of opium was followed by improvement, then the symptoms grew steadily worse. At the autopsy on the tenth day there was found a high intussusception (about 18 inches from the stomach) which was readily released by delicate traction. The intestine was in relatively good condition.

When considering operation, it often becomes a difficult matter to determine whether a given condition of ileus has been mechanically produced, or produced by peritonitis, for it is well known that the most vicious peritonitis may proceed without fever. Lejars has called attention to the fact that tubercular peritonitis may produce all the phenomena of intestinal obstruction without the slightest mechanical obstruction being present. Here the doubt should weigh in favor of operation, for since the operative treatment of peritonitis promises relatively good results, the operation is therefore specially indicated. In point it may be mentioned that Turner[9] operated on a case of obstruction due to tubercular peritonitis with prompt recovery and rapid disappearance of the peritoneal tubercles.

Volvulus or twisting of the intestine is a comparatively rare cause of obstruction. There are, in most cases, no symptoms sufficiently distinctive to admit of differentiation from obstruction due to other causes. Were it possible to diagnosticate these cases, they would in the very nature of their development and formation lend themselves rather favorably to treatment by abdominal taxis, or if in the colon, to treatment by injection or inflation. Rigorous shaking with manipulation of the abdomen, and stimulation of peristalsis by enemata may rarely untwist the involved gut. As a matter of record, however, it is rarely indeed that anything avails in severe cases except operation, and the same rules regarding early operation should apply here as apply in cases of mechanical obstruction of other forms.

The direct untwisting of the volvulus before great thickening and destructive changes have taken place in the obstructed part is often comparatively easy. A few days will place its reduction beyond the highest skill of the surgeon.

In early operation lies our greatest hope in all cases of mechanical intestinal obstruction. Naunyn collected from the literature 288 cases of operation for ileus. From the record of these cases it appears that by far the best results were obtained after operations on the first or second day after the beginning of symptoms. Results of laparotomy for intestinal obstruction in individuals suffering from hernia were particularly fortunate. These were, of course, not cases of incarcerated hernia, but cases of ileus as the result of stasis, adhesions and torsions in the neighborhood of the hernial openings.

The reason for the surprisingly good results in these hernia cases is to be sought in the fact that the operators knew where to look for the obstruction, and operated early. This fact forcibly impresses one with the value of accurate localization of the obstruction before operation, and early operating. The fact seems to stand forth in very clear light that in all diagnosticated cases of mechanical obstruction, and all cases in which there is doubt as to the nature of the obstruction, the so-called conservative methods, the administration of morphin, stomach lavage, injection and inflation of the colon are not only almost valueless, but often really dangerous. Morphin is especially treacherous. In giving it we "fall back upon the soft pillows of Providence," in most instances stultified and deceived, awaiting the messenger with the inverted torch.

In paralytic reflex ileus following abdominal operations, it must be conceded that the expectant plan of treatment is the better to follow. Unfortunately, it is not easy to distinguish this form from mechanical ileus; moreover, the former may develop into the latter. Here, again, doubt must weigh in favor of operation.

Post-operative adhesions producing obstructions must be dealt with promptly by reopening of the abdomen. In such adhesions are assumed to be present when oil and salts in generous doses fail to pass the intestine, and high colonic injections administered by one who really understands how to fill the colon with water fail to give relief.

The value of laparotomy as a purely diagnostic measure should not be underestimated. Notwithstanding Treves, Maylard and others have laid down very useful rules and precepts for differential diagnosis in intestinal obstruction, it is nevertheless very well known by those who frequently deal with these cases that the exact nature of the lesion is rarely made out before anesthesia has to some degree relaxed the abdominal wall, and usually not until the abdomen has been opened and the cavity explored.

In addition to the great number and variety of conditions which are well known as causes of intestinal obstruction, there are many which we would hardly consider as common causes of acute ileus, yet they are causes, and they are purely surgical conditions, and can be dealt with in no other way. For example, a case of obstruction due to cyst of the ileum and cecum is reported by Hochenegg, and Magnoux reports a case of invagination due to the presence of a myoma. This author collected from the literature reports of eleven cases in which this condition was caused by myoma. Morison records a case of obstruction due to polypus of the small intestine.

Neoplasms of the intestine may suddenly produce symptoms of obstruction of the bowel without previous warning. It is probable that in such cases hypertrophy of the muscularis above the obstruction compensates for the narrowing of the lumen, but with the lodgement in the constricted segment of some unusually large or hard mass of intestinal contents, an acute fulminating ileus suddenly develops. The sudden appearance of ileus does not always mean that a recent lesion is the cause.

It has been said by Treves that in ileus too much prominence must not be given to the mere circumstance that the bowel is obstructed, that to be sure obstruction of the bowel is often the prominent symptom, but not the sole basis upon which the malady depends. It can hardly be denied that the issue of a given case will

7. Fischer, N. Y. Med. Jour., Feb. 21, 1903.
8. Province Med., 1896, No. 5.
9. Lancet, April 12, 1902.

depend more or less directly on the length of time during which the intestine has been obstructed, regardless of whether the intestine be strangulated or plugged with its own contents. But mere plugging will not often produce the classical condition of ileus. The bowel may be completely plugged for weeks, and the patient make a good recovery. If, however, the intestinal wall be strangulated, its circulation blocked, the symptoms immediately become urgent: Here we must think of "strangled vessels," and beginning gangrene. Unfortunately, we too often confuse these cases of strangulation with mere obstipation or impaction.

It should be borne in mind that the condition of ileus with strangulation of the bowel is very rarely produced by mere plugging, and that when the symptoms of genuine ileus appear, nine times in ten the time of usefulness of the syringe and the enema is gone. I would not place a low appreciation upon the colonic douche. Its proper use requires brains and art and patience, and in no case should radical surgical means be considered until the colonic douche has been faithfully tried, but as a rule lavage of the stomach, inversion of the patient and colonic injection of oil, air and water are at best only palliative. Capillary puncture, abdominal massage and the administration of opium are perilous and reprehensible in practically all cases. With prompt diagnosticating, prompt operating and better operating the mortality will be steadily lowered.

It may be said that, as a rule, the urgency is not so great in obstruction of the large intestine as in closure of the small gut. In the former sedatives, hot stupes, taxis and enemata may be justly employed for a longer time than in the latter.

To some it might seem unnecessary to urge the necessity for early operation in cases of intestinal obstruction with ominous symptoms. This excludes mere obstipation, for the reason that impaction *per se* does not produce severe symptoms, as before observed, but physicians, for the most part, are for some reason not recognizing intestinal strangulation promptly enough, except it be consequent upon sudden descent of a hernia, and are not promptly advising operation.

It is a dangerous surgeon who counsels operation merely for the sake of operating, and who would operate in a "stable with a pocket knife," but he who bears the name of surgeon, and who is adequately equipped, and can provide a reasonably aseptic environment, but who stands by with folded hands, resigning these cases to Providence and the rectal douche, is ten times more dangerous. The surgeon who does not realize the limitations of his art is a dangerous man indeed, and he who is not aware of its possibilities is useless. But no man is more dangerous nor more useless in his community than the physician who would cling to a case of mechanical strangulating intestinal obstruction which he has been unable to accurately diagnosticate, and which he has not the facilities nor the intrepidity to treat in the only way which avails, that is by operation.

Abuse of the Medical School at Zurich in a Novel.—A Swiss authoress has written a novel which claims to portray the life of a medical student at Zurich. It is abusive in tone and has aroused much indignation. Professor Krönlein has written to the daily press explaining away the misconceptions, and a mass meeting of the students was held to protest against the statements in the book. The writer was a student in the literary course at the university. Her novel has been widely advertised by the protests, which is perhaps what she intended.

BACILLARY DYSENTERY (SHIGA).*

CHAS. F. MASON, M.D.
MAJOR AND SURGEON U. S. ARMY.
FORT SAM HOUSTON, TEXAS.

GENERAL REMARKS.

Dysentery has been, from the earliest times, a disease of great importance, and especially has this been the case in the tropics and in the camps of great armies in the field. My own impression, gained from something over two years' service in the tropics, is that intestinal disorders far outnumber all other diseases, and that of these, dysentery is of overshadowing importance; both on account of its high rate of mortality, and because of the invaliding which results from it.

In the medical history of the War of the Rebellion something over 259,000 cases of acute dysentery and 28,000 cases of the chronic type are reported to have occurred in the Federal Army alone; and, again, during the Spanish-American War the same disease played havoc among our troops in Cuba, Porto Rico and the Philippines; in the South African campaign it was also widely prevalent.

In the tropics it is endemic at all times, and its importance may be gathered from the observations of Strong that of 1,830 cases in soldiers admitted to one hospital in Manila in sixteen months, only one-third were returned from there to military duty, and that the deaths from dysentery in the Army in the Philippines were nearly four times as great as from any other single disease.

For many years an epidemic form of bacillary dysentery has prevailed in Japan in the late summer and fall; in 1899, there were some 130,000 cases, with more than 26,000 deaths.

The disease occurs all over the world, increasing in frequency and importance the nearer we approach the tropics. In the temperate zone it occurs sporadically, at times assuming an epidemic form, which, even in cold climates, may be widespread and fatal; and this is especially apt to be the case in institutions such as insane asylums, or other places where there is overcrowding and bad hygienic conditions. Dysentery is especially a disease of the late summer and autumn, and in the tropics is most prevalent toward the end of the rainy season, though it occurs at all seasons. Age and sex have apparently no other influence than that resulting from the greater exposure incident to the life of the male adult.

ETIOLOGY.

The dysenteries have been variously classified on epidemiologic, clinical and pathologic-anatomic grounds, and the varieties described by different authorities have been as numerous as their points of view.

On the one hand, some writers believe in the essential unity of all the dysenteries, while on the other it has been held that many forms of bacteria and several varieties of amebæ were each responsible for a particular form of the disease. Since the discovery by Losch, in 1875, of amebæ in the stools of dysenteric patients, these organisms have been regarded as the cause of tropical dysentery by many authorities. Between that date and 1897 nearly all the varieties of intestinal flora have been accused of being the causative agents of dysentery; but it was not until the latter year that Shiga, studying an epidemic of acute dysentery in Japan, was able to dem-

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

onstrate the constant presence, in the intestinal discharges and in the inflamed mucous membranes, of bacilli which were not found in the intestinal tract of healthy subjects or in those suffering from other diseases, and using the agglutination test of Widal, announced the year before for typhoid fever, proved that the blood serum from his dysenteric cases gave the specific agglutination with the newly-isolated bacillus.

Flexner, in 1900, found the same bacillus in dysenteric stools in Manila, but was not satisfied that it was a specific organism. Later in the same year Strong and Musgrave confirmed his findings, and expressed their belief in the specific character of the organism. Since then the same bacillus has been isolated from dysenteric stools by Krause in Germany, Flexner and Duval and Vedder in the United States, Deycke in Turkey, Frosch v. Drigalski and Conradi in Prussia in the dysentery supposed to have been brought from China during the recent war, and by Foulerton among the English troops from South Africa. Still more recently Duval and Bassett have isolated the same bacillus from the stools in the summer diarrhea of infants.

It thus seems to be established that there are, etiologically, at least, two distinct types of dysentery, one ordinarily acute and due to the *Bacillus dysenteriæ* of Shiga, and the other usually chronic without the Shiga bacillus in the stools, and due to the ameba dysenteriæ. To the bacillary types belong the epidemic dysenteries, and the sporadic dysenteries of temperate climates, as well as the summer diarrheas of infancy.

Bacillary dysentery, then, is an acute infectious disease due to the *Bacillus dysenteriæ*. It is characterized clinically by frequent loose passages containing blood and mucus, by pain in the abdomen, tenesmus, and more or less fever.

Anatomically, there is catarrhal inflammation, fibrinous exudation, coagulation necrosis, and finally, ulceration. The inflammation affects chiefly the large intestine, but sometimes the lower end of the ileum is involved as well.

THE BACILLUS DYSENTERIÆ.

These bacilli are small rods with rounded ends, resembling the typhoid and colon organisms. They are slightly motile, flagellated, stain with ordinary dyes, decolorize with Gram, and do not liquefy gelatin. Their resisting power is slight, being readily killed by weak antiseptic solutions, and by an exposure of half an hour to sunlight.

The bacillus is not readily found in the evacuations for the first few days nor in the subacute and chronic stages, but by the end of the first week it is found abundantly in the blood and mucus discharges. Toward the end of the attack it disappears to reappear in relapses.

In the intestines it is found in the fresh exudate and in the deeper layers of the ulcers. It is also found in the mesenteric glands, but never elsewhere.

The blood of dysenteric patients agglutinates the *Bacillus dysenteriæ* in dilutions of 1 to 20 to 1 to 130, depending on the severity of the case and the stage of the disease. According to Shiga, this alone is not sufficient evidence, and to be positive the agglutination should progressively increase in intensity. Agglutination appears, according to Strong, as early as the third day, and is usually marked by the fifth or sixth day; but, according to Shiga, it is not positive until the second or third week, and is not therefore, of great importance in diagnosis. It has been found as late as eight months after recovery.

The value of the bacillary diagnosis is lessened by the fact that the bacilli can not often be found in the early stages or in the mild cases, but when the morbid process is low down in the colon or in the rectum, they can generally be found without difficulty. Agar plates are made in the usual manner, and after twenty-four hours' incubation the colonies are examined, and those which are least developed and most transparent are tested as follows:

1. Agglutinating capability with immune serum.
2. Cultivation upon glucose-agar.
3. Cultivation in milk.

If the agglutination reaction is positive, no gas is produced, and milk is not coagulated, the microorganism is *B. dysenteriæ*.

Shiga gives the following proofs that his bacillus is the specific cause of dysentery:

1 It is present in all cases.
2. It is never found in other diseases or in healthy persons.
3. Its presence in the stools corresponds in degree with the intensity of the morbid process.
4. It is found in the lesions in the intestinal wall.
5. It, or its toxins, cause intestinal hemorrhage.
6. It is agglutinated only by the blood of dysenteric patients.
7. The agglutinating power of the blood increases in intensity with convalescence.
8. Pfeiffer's reaction is marked.
9. Immune serum is of therapeutic and prophylactic value.
10. The infection of man: this occurred in one case where a pure culture was intentionally given to a condemned criminal, and in another where a culture was accidentally drawn into the mouth. There have also been at least two other cases of accidental laboratory infection.

PATHOLOGIC ANATOMY.

The lesions are those of a catarrhal, diphtheritic and sometimes hemorrhagic inflammation of a part or the whole of the large intestine, and occasionally of the lower portion of the small intestine.

The inflammation is most marked opposite the flexures of the colon because of the tendency of fecal masses to lodge there and set up inflammation through irritation. The changes begin in the mucosa and extend to the deeper parts, in contradistinction to those of the amebic type, where they are most marked in the submucosa. There is extensive coagulation necrosis; but, according to Strong, few or no real ulcers. Shiga, in Japan, reports the colon as riddled with small, shallow, clean-cut ulcers. The anatomic picture, however, is very different from that of amebic dysentery, with its large, ragged ulcers and undermined edges, not infrequently resulting in perforation. The submucosa is much thickened and infiltrated, the peritoneal coat is sometimes inflamed, and occasionally there are adhesions and hemorrhagic spots. Perforation seldom or never occurs. In the superficial layers of the inflamed region all sorts of bacilli and cocci are found; but in the deeper layers and in the adjacent inflamed and swollen mesocolic glands the *Bacillus dysenteriæ* is found in pure cultures.

When the small intestine is involved the changes are the same as in the colon, except there is not so much thickening of the submucosa.

The liver and spleen are not involved, while in the amebic type liver abscess is common.

MODE OF CONVEYANCE.

The disease does not appear to be directly contagious. The bacillus must be taken into the mouth, and this is accomplished ordinarily through the medium of infected drinking water. It may occur through infected milk

or uncooked foods, and it is possible that it occurs from contamination by the dust from infected soil, and may be carried by flies in the same manner as in typhoid fever.

Intestinal disorders, indigestion, improper food, exposure to cold and wet, starvation, overcrowding, and, indeed, all bad hygienic conditions are strong predisposing causes.

CLINICAL HISTORY.

General Description.—The incubation period is very short, usually not more than two or three days, while in one case where a pure culture was intentionally swallowed, dysentery resulted within twenty-four hours. In another instance where a small quantity of a liquid culture was accidentally drawn into the mouth, the same result followed in less than forty-eight hours. In still another case where infection was supposed to have occurred through the rectum from the use of an infected chamber, the incubation period was twenty-four hours.

Ordinarily, the disease comes on suddenly. Often the patient goes to bed well and wakes up in the night with pain in the abdomen, followed by diarrhea, the movements becoming more and more frequent, until they consist almost or entirely of blood and mucus. The number of movements varies from a dozen to fifty or more, and may be over a hundred in the twenty-four hours. There is more or less fever, intense thirst, much restlessness, coated tongue, straining at stool, and finally the movements become almost constant and involuntary. The swollen and infiltrated intestine can often be felt through the abdominal wall, and is very tender on pressure.

The disease is ordinarily of short duration, not more than ten days or two weeks. Before the end of the second week many cases will have terminated in death or convalescence, or the disease may gradually assume a chronic type.

Special Features.—The mode of onset is almost always sudden. The facial aspect in the early stages is anxious and expressive of suffering; toward the end it becomes apathetic. Fever is generally present, of irregular type and variable in amount, often reaching 103 F. to 104 F.; toward the end there may be a sudden fall to subnormal, a very unfavorable sign, or there may be a sudden rise. Rigors are rare. The skin at first is hot and dry, but toward the end it may be cold and clammy.

The pulse is rapid and often small and weak; death usually results from cardiac exhaustion.

The tongue is coated white, and at first is moist, but later becomes dry and glazed. Vomiting is unusual, though it does occur. Thirst is usually marked and persistent. The stools, at first diarrheal, soon consist of mucus and blood only; in the chronic stages there is an admixture of pus. Hemorrhage is rare, but does occur.

Abdominal pain is commonly marked, and there is tenderness over the seat of the lesions in the colon. The spleen and liver are not ordinarily enlarged or tender.

The blood changes are not very important. The white corpuscles, especially the polymorphonuclears, are usually moderately increased, though they may be diminished, especially in the fatal cases. The red corpuscles, at first increased through the loss of fluids by the bowels, are later diminished on account of the loss of blood in the stools.

Pulmonary complications may occur, especially broncho-pneumonia. The nervous system is not markedly affected unless the lesions are high up in the colon or in the small intestine; delirium may occur toward the end of fatal cases.

The urine is often diminished in amount and retention occurs. Sometimes there is a small amount of albumen, and occasionally there is an acute nephritis. Parotitis is an infrequent complication.

Shiga states that the general symptoms are due to the absorption of the products of the solution of the bacilli themselves, and not to toxins produced by them; that these symptoms are not so marked as in typhoid fever is due to the location of the lesions in the less readily absorbing large intestine. Sometimes the lesions are higher up in the small intestine, and then the disease is much more grave and the toxemia marked. Symptoms such as high fever, headache, pains all over the body, sleeplessness, stupor, delirium, ecchymoses, etc., appear, and when the rectum is much involved, tenesmus is marked. The disease has a constant tendency to ascend, and the higher up the lesions the more marked the toxemia, the larger the stools and the greater the gravity of the case.

ASSOCIATION WITH OTHER DISEASES.

The older writers, particularly Manson, seemed to think that the disease is often associated with malaria; but this view is opposed by Strong as a result of his experience in the Philippines.

There have been, however, a number of cases of double infection with the ameba and with the Shiga bacillus.

There are two types, or rather stages, of the disease; the acute form or ordinary epidemic dysentery of the tropics and temperate zones, and the subacute or chronic stages following the acute.

DIAGNOSIS.

Local rectal troubles causing blood and mucus discharges, such as hemorrhoids, polypus, malignant disease, etc., are to be excluded by direct examination. The most important differentiation is that from amebic dysentery, and this is often not possible from a consideration of the general symptoms alone. The most important points are the sudden and severe onset, the rapid course, high mortality, and epidemic occurrence of the Shiga dysentery, as contrasted with the more gradual and milder onset and course of the amebic disease and the endemic prevalence of the latter. The amebic type is, however, sometimes acute in its onset. Liver abscess seldom or never occurs in the bacillary disease, while it is common in the amebic form. In amebic dysentery, except when complicated with liver abscess, toxic symptoms, such as fever, malaise, headache, anorexia and nervous symptoms, seldom occur.

The specific tests are the only reliable ones; the isolation of the bacilli from the stools and the agglutination tests for the Shiga organism, and the finding of the ameba in the stools in the amebic type. The bacilli are found in the stools in all severe cases of Shiga's dysentery as early as the end of the first week in the acute stages, and sometimes in pure cultures. They may not be found in the later stages, and they are never present in the intestinal tract of healthy persons.

PROGNOSIS.

This depends on the severity of the epidemic and extent of the lesions. If the rectum and sigmoid flexure only are involved, the prognosis is favorable, while if the whole large intestine, and especially a portion of the small intestine is involved, it is very unfavorable. Nervous and other toxemic symptoms indicate such involvement, and are hence unfavorable signs. Failure of the agglutination reaction to increase in intensity is also a bad omen.

The disease is always a grave one, the mortality ranging in the Japanese epidemics from 30 to 40 per cent. Recovery is rare in the more severe cases, and death usually occurs in the first ten days. Those who do recover are left very much weakened and emaciated, but usually without the digestive disturbances which so often follow amebic dysentery.

PROPHYLAXIS.

In the treatment the same precautions to prevent extension of the disease are required, as in typhoid fever; the most important of these consists in thorough disinfection of the discharges from the bowels and everything liable to have been contaminated by them, including the hands of attendants and instruments and appliances used about the patient. Personal prophylaxis includes also the use of water that has been sterilized and the avoidance of uncooked fruit and vegetables. The disease is a preventable one, and with military commands it should be prevented whenever it is possible to control the water and food supply of the men.

TREATMENT.

In the acute form the first essential is absolute rest in bed, with sufficient covering to protect from cold and draughts. Diet is also of the utmost importance, and should be exclusively liquid, and of such a nature as to be completely digested in the stomach. Milk is the best food, and may be given plain, peptonized or diluted with carbonated water or lime water; in the form of koumyss it is also well borne. All drinks should be tepid or warm, and given in small quantities at a time, and at frequent intervals. When milk is seriously objected to or can not be borne, strong broths of beef, mutton or chicken may be used; albumin water is of value in very severe cases. Stimulants may be given if needed, and the best is good brandy in the form of milk punch, or an occasional egg-nog.

The success which has been attained in Japan with the specific serum treatment instituted by Shiga gives that method the first rank in the consideration of therapeutic agents. Having had no experience with the method myself, I quote from Shiga's own article in the Twentieth Century Practice:

IMMUNIZATION OF HORSES AGAINST DYSENTERY.

An agar culture of the *B. dysenteriæ* which has been maintained at the incubator temperature for twenty-four hours is emulsified in normal saline solution and heated at 60 C. for one-half an hour. This mixture is then inoculated subcutaneously into horses in the usual manner, beginning with small doses which are gradually increased in amount. The immunization can be more easily produced if immune serum is added to the emulsion of the dysenteric bacilli, because abscesses which reduce the vitality of the animal are often produced at the site of the inoculation when bacilli alone are employed.

PRACTICAL SERUM TREATMENT.

Dysenteric serum, like typhoid serum, is bactericidal, but in practice the former gives much better results than the latter. According to my opinion, this is due to the localization of the lesions and the toxic symptoms. In dysentery, the lesions are usually localized in the rectum and lower portion of the large intestine, whose physiologic function is principally mechanical, and where absorption of the food does not take place as in the small intestine. The toxic symptoms are intimately connected with this localization, against which bactericidal serum is valueless. Such symptoms in dysentery are happily less prominent than in typhoid fever. This is the chief reason for the favorable influence of dysenteric serum. This conception also accounts for the very unprofitable prognosis in enterodysentery.

RULES FOR ADMINISTRATION.

In accordance with my researches I have formulated the following rules for the administration of dysenteric serum for use in the Institute for Infectious Diseases in Tokyo:

1. In mild cases the serum is inoculated once in a dose of 6 to 10 c.c.

2. In cases of medium severity the serum is twice inoculated in doses of 10 c.c. The interval is from six to ten hours.

3. In severe cases the greatest quantities of serum are inoculated (about 60 c.c.). The daily dose does not, however, exceed 20 c.c.

By serum treatment the disease in its first stages is quickly cured or remarkably ameliorated. In advanced or inflammatory stages the effects produced are about as follows: The number of stools is markedly diminished (generally reduced by halves for three successive days, followed by rapid recovery), the tormina and tenesmus decrease, the blood in the stools diminishes or entirely vanishes, the abdominal pains lessen, the fever vanishes, the appetite increases, and the general condition is much improved. In the ulcerative stages the action of the serum is not so pronounced as in the earlier stages, nevertheless healing of the ulcers with cicatrization often takes place. In such cases the fever is reduced, the number of stools is markedly diminished, the general condition is improved, and the appetite increases. In this stage even the results obtained are far better than those given by any other method of treatment.

By the serum treatment the course of the disease is shortened in those who recover, and lengthened in those who die. Of the 510 cases which I have treated (298 with serum and 212 with drugs) the entire course (counting from the beginning of the sickness to the discharge from the hospital) was on the average as follows:

	Recovered.	Died.
Serum treatment	25 days.	16 days.
Symptomatic treatment	40 days.	11 days.

The mortality of dysentery varies according to the climate, the epidemic, etc.; in order to estimate properly the value of the serum treatment I will here record the mortality in hospital treatment.

The mortality by the use of the serum treatment was reduced one-third below that given by symptomatic treatment, and was less than one-half the minimum obtained by such treatment.

MORTALITY IN HOSPITAL TREATMENT.

Year.	Place.	Treatment.	Number of Cases.	Deaths.	Percentage of Deaths.
1895	City Hospital	Symptomatic.	38	22	55.0
1896	City Hospital I.	"	221	86	39.0
1896	City Hospital II.	"	6	2	33.3
1897	City Hospital I.	"	336	143	42.4
1897	City Hospital II.	"	4	1	25.0
1897	City Hospital III.	"	767	304	39.6
1897	Inst. for Infec. Dis.	"	34	8	23.5
1898	City Hospital I.	"	178	73	42.0
1898	City Hospital II.	"	385	141	36.6
1898	Inst. for Infec. Dis.	Serum.	65	6	9.2
1899	City Hospital I.	Symptomatic.	98	32	32.6
1899	City Hospital II.	Serum.	88	11	12.5
1899	City Hospital III.	Symptomatic.	481	105	22.0
1899	Inst. for Infec. Dis.	Serum.	105	5	8.5
1900	Inst. for Infec. Dis.	"	40	5	12.5

Certainly this is a showing which encourages us to give the serum treatment a careful and extended trial. But Shiga says:

Whether or not serum-therapy is employed, suitable cathartics and enemata should always be administered, since these tend to limit the upward extension of the disease. For this purpose I generally order 0.5 grams of calomel, to be given twice, or 10 to 15 c.c. of castor oil, which is to be given but once. Thereafter, enemata of 1 per cent. saline or soda solution should be given once or twice daily. Combined with the serum treatment I generally order acid or alkaline drinks or red wine.

MEDICAL TREATMENT.

This may be considered under two headings, antiseptic and eliminative treatment. Of antiseptics, those

usually employed are calomel, bichlorid of mercury and salol. All these have been highly praised and extensively used, but with the exception of calomel, which at times is very useful as an eliminative agent, it is doubtful if any of them have real value.

The most important eliminative agents used are the saline laxatives, especially the sulphates of soda and magnesia; ipecac in large doses is also highly recommended.

These remedies act first by emptying the bowels of all irritating fecal matter and then mechanically flushing them out, sweeping out at the same time many of the bacilli and their toxins.

Some physicians use the salines in large doses and only at the beginning of the disease, while others use small doses frequently repeated until blood and mucus disappear from the stools.

The ipecac treatment is very popular with the British, more especially in the British Indian service, but it has never gained much of a foothold among the profession either here or in our tropical possessions. In this method no food is given for several hours, then a mustard plaster is applied to the epigastrium and twenty or thirty drops of laudanum given by the mouth; half an hour after the laudanum two grams of ipecac are given in bolus or capsule, and the patient kept perfectly quiet with head low. If the medicine is rejected by vomiting it is repeated after an hour or two; if it is retained it is nevertheless repeated after eight, ten or twelve hours, according to the effect produced, the object being to secure a feculent movement free from blood and mucus.

My own plan, as a result of experience gained in the tropics and the southern states, is to give 10 grams of Epsom salts in half a glassful of water every hour until a movement is obtained free from blood and mucus. This method is combined with irrigation of the lower bowel with warm normal saline two or three times a day, and as soon as the movements assume an ordinary diarrheal character astringents, such as bismuth subgallate in large doses, combined perhaps with a little Dover's powder, are given every three or four hours; should blood and mucus reappear, the saline flushing is repeated. The lower down in the bowel the lesions are seated the more important becomes the local treatment by irrigation.

In convalescence great care is required in the management of the diet. These patients are usually greatly weakened and emaciated, and a slight indiscretion in regard to food will often cause a serious relapse. Only liquids or very soft and digestible solids should be used for some time after the movements become normal. A change of climate or a sea voyage greatly hastens recovery, and for patients in the tropics is often essential.

TREATMENT OF THE SUBACUTE AND CHRONIC STAGES.

In the subacute and chronic stages of the disease the treatment is somewhat different, but even here salines may often be used with advantage in the beginning. Local treatment is, however, of the first importance in these cases; the patient should be given an anesthetic, the sphincter well stretched, and the rectum carefully examined with the speculum to detect ulcers. These ulcers will often be found with a little pocket at the lower end in which fecal or other foreign matter lodges, keeping up the irritation. These pouches must be slit up to the bottom, scraped with the curette, or touched with pure carbolic acid or lunar caustic; after this the use of warm saline injections two or three times a day with proper diet suffices to effect a cure. When the lesions are higher up nitrate of silver injections, 1 to 500 or 250, are given every day or every other day; the injections should be large, two or three pints, warm, and given slowly through a tube introduced 12 or 15 inches; the patient should be in the left lateral position with the hips raised. Internally, large doses of dermatol are useful in these cases.

MALARIAL DYSENTERY.*

WILLIAM BRITT BURNS, M.D.
MEMPHIS, TENN.

One has but to review the literature of dysentery to arrive at the conclusion that there is no fixed etiologic factor in this disease; that the lesions, which are mainly confined to the large intestine, are quite characteristic, but are induced by several different agents, is a pretty constant finding, and is worthy of consideration.

The *Amœba coli* is designated as the specific causative factor of dysentery, but here one is confronted with the fact that these bodies are found in less than one-half of the cases of all varieties and stages of the disease, and that the colon may be the normal habitat of amebæ, not only of this, but other amebæ—*Amœba guttula, diaphana, vermicularis, oblonga, reticularis and proteus*—which, it may be, are quite as culpable as *Amœba coli*. Moreover, these bodies are usually accompanied by other organisms, some pathogenic, and others which, by the proper environment, may be made pathogenic. Again, injections of amebic stools into the bowels of laboratory animals have not produced dysentery, and on the other hand, ameba-free stools injected in like manner have produced the flux. *Amœba coli* occurs nearly constantly in the pus of about half of the cases of liver abscess from dysentery; bearing out the contention of Councilman and Lafleur that amebæ are found, not alone in the pus and on the walls of intestinal ulcers, but in the tissues around them, they could not, therefore, reach the liver without some such portals of entry. I quite agree that the *Amœba coli* is one of the agents in the etiology of dysentery.

The work of Shiga, Flexner and others have given the profession a ray of hope looking to the minimizing of the agents of this great scourge, but up to the present we are only able to say that there are "forms of dysentery," under which heading "several diseases unlike in their etiology and pathologic anatomy and, occurring under different conditions of climate and locality, although resembling each other to some extent in their symptoms." Thus we have dysenteric and diarrheal symptoms accompanying typhoid infection, pneumonia, bronchitis, hepatitis, abscess of the liver, etc.

Celli and Fiocca believe that the *Bacterium coli communis* is the etiologic factor in dysentery; this in connection with a bacillus resembling the typhoid bacillus and streptococci induce dysentery. Flexner has observed in the Philadelphia Hospital one case of dysentery, where the *Bacillus dysenteriæ* was found, and states that further observations are necessary to determine definitely whether this form of disease prevails in this country.

In short, it seems the part of wisdom to admit that in so far as there is a distinct, definite causative factor in the production of the fluxes, we are largely in doubt.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

Thus, desultorily, I am lead to the subject of this paper. I could not better begin than by quoting from Manson: "In respect to geographic distribution and certain epidemiologic points, tropical dysentery bears a close resemblance to malaria. Like malaria, although dysentery is found in temperate climates, in them it is, with exceptions, a comparatively rare and mild affection. Like malaria, as we approach the Equator dysentery tends to become more common, and in type more severe. Like malaria, it is endemic in certain spots, where it often appears in sporadic form, and, at times, in limited local epidemics. Like malaria, it may extend beyond these endemic spots and involve more extensive tracts of country. Like malaria, it appears to have a predilection for low-lying damp places; and, like malaria, when occurring in temperate climates it is most prevalent in the late summer, or in early autumn. Like malaria, it tends to disappear on the cultivation and drainage and improved sanitation of a country."

In looking over the "Medical and Surgical History of the War of the Rebellion," I have been struck by the apparent accurateness of the observations of the medical officers on the "Pathologic Anatomy and Pathology of Malarial Disease," and the deductions drawn therefrom, measured by the present-day knowledge of the pathologic conditions brought about by the malarial parasite.

The postmortem notes, so far as required for our subject, are as follows:

Stomach.—In 21 of the cases the condition of the stomach is not stated; it was normal in 5 and constricted in 1. In 13 cases a morbid condition was specified thus: In 4 the organ contained a green-grumous or mud-like liquid; in 3 its mucous membrane was congested; in 1 softened; in 1 slate-colored; in 1 thickened, and in 4 ecchymosed.

Intestinal Canal.—In 6 of the 40 cases the intestines were reported healthy; in 9 their condition was not stated. In 13 of the remaining 25 cases the large and small intestines, so far as can be ascertained from the phraseology of the reports, were both affected. Five of the cases were much congested or inflamed, but not ulcerated; in the first-mentioned, for instance, the canal was almost black from the engorged condition of the capillaries, and coagulated blood was found in its interior. In 1 of the 13 cases the mucous membrane was softened, and in 7 ulcerated; in 2 of the latter the duodenum alone was ulcerated, although the canal was generally highly congested; in 1 the ulcerations were reported as slight; in 1 as old; in 1 as large and in 1 as small, and in 1 as associated with a congested condition of the mucous membrane. In 6 of the 25 cases the condition of the small and large intestines is specifically stated: In 1 both were inflamed, but the patches of Peyer were not diseased; in 1 both were much congested and ecchymosed; in 2 deposits of black pigment were found in the large intestine, while the ileum in 1 was but slightly congested, and in the other merely stained with bile; on the other hand, the patches of Peyer in 1 presented the pigmented appearance, while the rectum was ulcerated; in 1 the mucous membrane of the ileum was softened and thickened, that of the colon congested. In the remaining 6 of the 25 cases the small intestine or ileum only was affected. In 3 it was congested, in one of which the patches of Peyer and the solitary glands were enlarged; in 1 it was ulcerated; in 1 congested to a purple color, which presented a deeper tint in the apices of the solitary glands, although the patches of Peyer were unaffected; in 1 also there was a deeply colored congestion which was especially marked throughout the jejunum.

I might quote the parallel observations of Maillot and of Laveran on the incidence of dysentery in malaria among the French troops; many others have contributed thoughts along this line. Craig, in his book on Estivo-Autumnal Malaria, leans very pronouncedly to the plasmodium as a causative factor in diarrhea and dysentery.

I have seen many, many times cases of dysentery respond promptly to quinin treatment. I am not now possessed of the case notes in these cases, but I remember well to have had a small epidemic of dysentery, each case of which began with the algid form of pernicious malaria. These were not merely of the catarrhal character, but there was "chopped meat" discharges, evidence of some sloughing. All of these cases—about 12 in number—responded to ordinary antiseptic irrigations, gland arousement and quinin in a week or less. Convalescence rapid.

Lastly, malarial parasites have been found not infrequently in the vessels of the mucosa and submucosa in cases of malarial dysentery coming to necropsy.

NOTE.—The discussion on the symposium including the papers of Drs. Mason and Burns will follow later.

TRAUMATIC PNEUMONIA.*

W. T. ENGLISH, A.M., M.D.
PITTSBURG, PA.

The compound term "traumatic pneumonia" implies association of injury with disease. Its ample interpretation concerns alike surgical and medical science. The Greek word "trauma" is very near to that of the English word "injury," both as to use and significance. Pneumonia is a medical appellation given a disease involving the presence of specific germs, and various changes in the air vesicles, parenchyma and associated structures of the lungs. "Pneumonitis" and "inflammation of the lungs," formerly used to designate this malady, have given place to the more liberal term "pneumonia." The use of the latter designation does not commit us to any theory as yet in dispute, and is in harmony with empiric evidences, as well as bacteriologic demonstrations of the present. Under whatsoever garb or name, and whether recorded in the chaos of lapsed eons or mingling with the dust and tumult of twentieth century activity, pneumonia has been and continues to be the assassin of human comfort, health, life and medical theory. Its autobiography is written in signs and symbols so legible that "he who runs may read," without betraying its origin or end. It shows no respect for time, place, age, sex or condition. Now it may be individualistic, again communistic, and anon socialistic. The frontier medical man "sees it in the clouds and hears it in the wind." The bacteriologist, confused by its multo-coloring, announces it an emanation from pleural sources.

Trauma is one causative agency in the awakening of pneumonia not yet accorded full recognition as a medical or surgical entity, which appeals to the consciousness of the physician of this age as never before. The importance of the subject augments with every step of human advance involving the utilization of energies and mechanical inventions unknown to our forefathers.

With "traumatic pneumonia" the profession is not as familiar as it should be, neither is it equipped with

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank A. Jones and W. S. Thayer.

ample literature from those who have been the awed but mute witnesses of its consequences.

Surgical science, as displayed in the war between the north and south, hinted at the subject, and the immortal Hamilton observed that "The shock produced by a musket ball is sufficient to cause a rupture of some of the more superficial pulmonary vessels, and in other cases it gives rise eventually to pleuritis, or even pneumonia." He further says "a missile may impinge upon the thorax and without causing rupture of the skin or anything more than a slight abrasion, may fracture the rib, rupture the lungs, or some of the large blood vessels, or even tear open the heart itself."

Reidinger gave the name of "concussion of the chest," or commotio thoracica, to a series of cases of this character, but produced in various ways which were remarkable for their fatalities.

Litten, a more recent and copious writer upon the subject, recognizes the large influence of trauma upon the occurrence of pneumonia, and concludes that, "lobar, croupous (or fibrinous) pneumonia may arise as a sequel to violence upon the thorax, where no external signs appear." In his terminology he uses the name "traumatic pneumonia" for those cases following penetrating wounds in the lungs, and reserves the term "contusion pneumonia" for those resulting from external force producing concussion of the lungs.

Rezerot notes that "the results of injury may show pneumonia, localized spots of catarrhal pneumonia, and even interstitial thickening of the lungs."

Stephen Paget, a most reliable and capable observer and author, expresses himself thus: "We are tempted to make light of a general injury of the chest, unaccompanied by fracture, or by a serious wound of the soft tissues. But apart from the fact that very grave and even fatal results may follow a blow or a bruise over the chest, which seemed in itself insignificant, general injuries of the chest are sometimes attended by changes so unexpected and so obscure that they need careful consideration." In conclusion, he adds: "We are bound, therefore, not to think lightly of contusions of the chest merely because there is no fracture or external wound."

Pirogoff is authority for the statement that "such injuries are at least as dangerous as penetrating wounds."

Stern, who has made a special study of pneumonias from all causes, places the statistics of those produced by trauma at 4.4 per cent.

From all this we must infer the importance of the subject presented, and be also impressed with the necessity for careful inquiry into the causal factors in all classes of pneumonia, and especially those preceded by injury, no matter how trivial the objective evidences of trauma may appear. We must not forget that accident and fright may be factors in the production of traumatic pneumonia. Some recent authorities claim that fright is the first element of danger, although manifestly greater in some than in others. In our study of the factors contributing to the occurrence of traumatic pneumonia, we need not prove faithless to the theory associating the disease with the diplococcus, as it is a fact that the micro-organisms are present in the expectorations of those suffering from traumatic pneumonia.

The purpose of this paper is the consideration of those cases of traumatic pneumonia which appear from contusions, and, as far as possible, refrain from mention of those due to penetrating injuries of the lungs, or those including fractures of the bones or cartilages.

The question arises, "how is it possible for a jar or force expended upon the external surface of the yielding thorax to be so transmitted as to do violence to the contained viscera, and especially the elastic lungs?" We may understand why the delicate tissues of the brain may be injured by slight concussion, even by contrecoup or force upon the lower end of the spine, but we are naturally inquisitive about like possibilities in the lungs. The normal elasticity of the chest, in the majority of cases, is capable of rendering *nil* the accidental forces which antagonize it. The extremely young will resist a crushing weight, as that of the wheels of a wagon, to which the mature thorax would yield. However, a stroke of 100 to 300 pounds, carrying with it past the point of contact upon the chest all of the force not antagonized by the resistance offered, will cause the elastic walls to impinge upon the lungs with dangerous results, corresponding to the degree of thoracic elasticity. It would be more to the pulmonary disadvantage if the lungs were surprised by accident during full inspiration than if occurring at the end of expiration. Unfortunately, the former is the attitude of the lungs at the instant when the largest number of injuries are received. Fright is associated with 90 per cent. of chest injuries. In more than half of these fright prompts a gulp of air, closure of the glottis, rigidity of the diaphragm and other muscles of respiration and a fixidity of the thorax. There is also an attempt to free the arms, as in the attitude of self-defense. The chest is never guarded in this pose, instinctively responsive to the primal law of nature—self-preservation. Fright has not time for appeals to the ideational centers. The frightened human "holds his breath," and a stroke or fall on the chest is often received in the position of pulmonary disadvantage. To this condition of the chest is often added an advantageous angle for the force because of the unfortunate position assumed by the individual.

Hamilton describes the mechanism of force thus: "The ribs with their cartilages are bent inward violently and made to encroach very far upon the contained viscera, and serious lesions may be produced before the bony parietes are fractured."

Thus far we have considered normal conditions of the thorax and lungs, and the inference is that the force required to produce injury to the lungs varies with the age, elasticity of the chest, position of the lungs in the respiratory act, the exact angle at which the stroke may be received, and the individual factors.

It must be remembered that if a blow impinges upon the chest walls it is distributed to adjacent structures much as the sound waves in the air, amplifying and making greater impressions upon localities most easily influenced.

Peyrot claims that if a blow is received by the chest it is distributed to adjacent structures, but the lung itself is independent of this movement. Any want of elasticity, however, will favor yielding under stress, and injury results. This is direct injury. Moreover, there are numerous foci of latent weaknesses and chronic maladies in the average lungs which are liable to be affected by force thus extended. Tubercular diseases, pulmonary emphysema and congestions, as from heart disease, alcoholism, etc., act as predisposing causes and give wider range to traumatic influences than would be available in normal conditions.

Adhesions may influence changes in a mechanical way in parts remote from the seat of force. The jar may

awaken a latent disease protected hitherto by areas of inactivity and solidification.

Many intrinsic and extrinsic causes must be considered in the efforts to account for pneumonia which will appear peculiar to each case and constitute the individual factors. One thought must be ever present with the physician called to examine the chest after injuries, and that is the universal possibility afforded everywhere for acquiring traumatic pneumonia. Pneumonia is today made available to all. The wholesome and the unwholesome, the wise and the unwise, are almost equally liable to become its victims. Nor is it needful that they await the incubation period of the pneumococcus or streptococcus, but by thoughtless dalliance during the millionth part of an instant in the way of a rapid transit electric car or a twentieth century juggernaut—the automobile—pneumonia begins to weave the network of death in the lungs. From the cultivated "interference" of the foot ball field, the polite fistic arena and other places for the display of athletic proficiency, as well as amid the hum and whir of mill and workshop, and from every point of the world where the strenuous life of the twentieth century thrills human kind, traumatic pneumonias are reported. These augment the numerical statistics of pneumonia and increase the mortality.

Interest in the subject is enlarged also by its medico-legal aspect. It is required that the physician commit himself most positively and under oath to the theory of its cause and consequences. The numerous incidental notations which concern the history, the onset, complications and sequelæ will be investigated by life assurance companies, accident insurance associations, and other corporations or individuals charged with liability, and tedious trials and litigations demand of the attending physician the most careful, exact and conscientious judgment of which he is capable.

The question will arise, "is the pneumonia an accidental or coincidental circumstance?" This must be answered by the physician in every case involving medical and surgical possibilities, whether before the legal judiciaries or the bar of his own conscience.

The responsibility of the physician ends not with the apparent cure of the acute conditions, but continues without limit because of diseases which develop later and may be regarded as sequelæ.

Pleurisy, pneumothorax, pyothorax, empyema, phthisis and almost every malady in the category of chest disorders have been charged to injury received at some period in life. The postmortem evidences have been most effective in some investigations.

When a physician is called to a case of injury liable to produce traumatic pneumonia he will probably find a rapid pulse and accelerated respiration, and in fully 65 per cent. the sputum will show some blood within a few hours, if not immediately. The shock is the first element of alarm demanding attention. The respiration reaches 60 to 70 per minute, but is not so common a symptom in adults as in children, and does not always correspond with the extent or gravity of the injury. Hamilton notes that "expectorations of blood in most cases occur immediately—frequently not until after the lapse of several hours, or even days, but it is rarely seen after the fifth, sixth or tenth day." The writer observed in a recent case that spitting of blood continued until the fourteenth day after the injury. Dyspnea may be absent, and no duskiness of the face, and nothing to suggest injury except disturbed breathing. No general or extensive contusion may appear with the history of a slight blow, affecting one portion of the chest and yet the shock be most disastrous. A condition of syncope immediately following trauma may be due to direct stimulation of the vagi, or to direct cardiac compression. The depressor nerves and the sympathetic may also act as causative agents in lowering the blood pressure during any prolonged period.

The examination of these cases must be conducted with celerity, and the physician should endeavor to give the patient as little discomfort as possible. The horizontal position is usually the safest and one causing least suffering. The external bruise or contusion will heal rapidly, and the pneumonia usually gives its characteristic signs and symptoms after forty-eight hours from the time of the contusion. This pneumonia may or may not be promoted by a destruction of continuity of the lungs, pleura or bronchial tubes, and the mechanical jar of the impinging stroke cause a slight tenderness or soreness which may arouse latent pneumonic energies which otherwise might have continued in abeyance or be counteracted without reaching the dignity of a pneumonia. Slight concussions are rarely dangerous in a purely surgical sense, but can thus directly prove fatal, and it is well to remember that infection may come to the lungs thus crippled and phthisis speedily follow. The relations of time to these consequences are very variable, and it is not safe to say that pneumonia coming on a fortnight after the injury of the lungs is not due to concussion, nor is it to be regarded as a safe position to assume that a phthisis, following years after the lungs have shown apparent cure, bears no responsibility as a causative agency. The rusty sputum is likely to succeed upon the streaked sputum as soon as the pneumonia reaches its second stage. Moreover, the diplococcus is to be found in traumatic pneumonias as easily as in cases free from injury. It is a fact that these germs are to be found in the mouths of most healthy people.

Jobert separates into three degrees, or classes, these injuries:

First—Hemorrhagic punctata from capillary rupture, the parenchyma remaining intact.

Second—Includes those in which small ruptures exist in tissue, including alveoli, bronchioles and vessels about them.

Third—Tears of the lungs, bronchi and vessels.

No systematic or conventional method of observation or treatment can be provided for these cases, as each is a law unto itself, yet a review of a few of the records may prove of advantage.

E. Block tells of a man 41 years old falling and striking upon the lower portion of the right side of his chest, who developed signs of pneumonia the following day in the right lower lobe. No chill was recorded, and the crisis occurred at the end of the fourth day. Bloody sputum was absent. It is assumed in the report that a moderate injury of the lungs may have given opportunity for the invasion of the pneumococci, which were found in the sputum.

Dr. R. A. Booth, physician to the City of Pittsburg, is quoted as having a case of traumatic pneumonia a few days ago in the hospital, caused in a man 62 years old, and which proved fatal in the fourth day. At the hospital the patient told the attendants he was injured by falling down stairs. A number of cases gathered by research have been charged to similar accidents.

R. E. Lord has placed on the list a case of injury to the chest by striking against a desk followed by hemoptysis and consolidation of the lung immediately under-

lying the seat of injury. This is one of a number of reports of cases of traumatic pneumonia resulting from violent contact of the chest and the edges of desks.

Dr. A. Koch adds the case of a man aged 38 years who fell from a height and received a severe contusion of the left side of the thorax, and in less than forty-eight hours after died in the hospital. Postmortem examination showed croupous pneumonia, with red hepatization and pneumonia bacilli. The man was free from disease at the time of the accident, and the ribs were not injured.

A case of "contusion pneumonia" contributed by Aufrecht shows that the pneumonia occurred on the side opposite to the injury, which later was produced while pushing a wheelbarrow heavily loaded, when the left handle struck upon the left side of the chest. The man was 38 years old, and up to the time healthy. About ten hours after the accident pneumonia appeared on the right side. Three days after the injury he died. An autopsy showed pneumonia of the right base.

During a professional experience of over three decades there have been personal opportunities afforded for observation in the City of Iron and Smoke. The list of traumatic pneumonia, inclusive of fractures of the bones and cartilages, as well as those due to contusions and concussion, challenges credulity. Those within the scope of this paper are not so numerous, and a brief recitation of some of these will be interesting. A man aged 29, of good health and uncertain family history was thrown upon his back and rudely tossed against the front door of an electric car which had deserted the track at a sharp curve and collided with a telegraph pole. He was completely disabled, and was lifted into a carriage and conveyed to his home, a distance of five blocks. Dyspnea, with the psychologic evidence of excessive alarm, were associated with blood-spitting and complaints of unease within the thorax. Appropriate treatment speedily annulled the immediate signs of the shock. Perfect quiet in the recumbent position was secured, but notwithstanding these precautions, a traumatic pneumonia was in evidence before the conclusion of the first forty-eight hours, without any special features, except that the hemoptysis gave place to rosy sputum on the third day. This case terminated by lysis, and was followed by prolonged convalescence. Three months later hectic symptoms appeared and tubercle bacilli were found in the sputum. A few days short of two years after the accident the life terminated. A suit was brought by the relatives against the street railway company, whose legal advisor made satisfactory settlement.

A man aged 61, of reasonable health, who was filling the duties of labor boss, was caught between an overturned wagon and the side of an excavation. His release was affected after about eight minutes. He was faint and suffered from a sense of suffocation. The employment of alcoholic stimulants, administered by the mouth, and crude attempts at artificial respiration gave him some relief until medical aid arrived. Hypodermatic use of strychnia and brandy were resorted to with good results. He was removed to his home and placed in the most restful and quiescent condition possible. This man developed a pneumonia before the end of the first twenty-four hours, in which the temperature range never exceeded 103.8. The pulse, which was 148 during the period of shock, fell to 118 after the lapse of ten hours, but fluctuated between this and 138 without apparent cause. This case showed no real abatement until after the fourteenth day, when the pneumonia ended rather abruptly, and all symptoms disappeared gradually. The patient resumed his former occupation at the beginning of the sixth week.

A man aged 57 years was walking on the railroad track when he was struck by an engine and precipitated over an embankment of 16 feet, sustaining fractures of the right humerus in two places. The force of the stroke caused the arm to infringe upon the right side of the thorax, producing an extensive contusion over the entire side. Blood-spitting appeared immediately. After sixteen hours, and without chill, the temperature reached 103.8, respiration 44 and pulse 128. The signs and symptoms of pneumonia continued until the seventh day, when they suddenly diminished and convalescence was rapid, leaving only the external surgical conditions for treatment. After a lapse of twenty-eight months this man continues in perfect health.

Dr. Ulysses Strouss of Beaver, Pa., reports a case in a man aged 32, standing on the rear end of his wagon unloading coal, when his horse suddenly started forward and he was thrown violently to the pavement, alighting on the posterior superior portion of the chest. He spat blood in a few minutes after the accident, which was succeeded by traumatic pneumonia, terminating by crisis on the fifth day, and there was rapid recovery. Six months have elapsed and no unfavorable symptoms have appeared.

A case illustrative of the lapse of time before betrayal of the results of injury is that of a man riding in an automobile and colliding with an electric car, precipitating him to the pavement with considerable force, upon the posterior aspect of the chest. The injury did not retire the subject from his duties until after the expiration of ten days, when a large quantity of dark blood was expectorated, in which the molds of the bronchial tubes were plainly demonstrated. The temperature ranged during four days between 102 and 103, when it ended by lysis. The physical signs were those of bronchopneumonia, with copious mucous râles of varied size, and cough and respiration of suffocative character. The sputum was examined carefully for tubercle bacilli with negative results. Subsequently, by the city physician, with like report. A third specimen expectorated in the writer's presence, and divided into three parts, was examined by three different persons, and several bacilli discovered by one. The last reports have been that the patient is perfectly well. This accident occurred ten months ago.

A man aged 41, lumber dealer, and of good habits and health, was thrown from the steps of a rapid transit car while attempting to alight, the signal to start being premature, and he received a severe stroke upon the anterior portion of the chest walls. He was taken to his hotel and placed in bed. No fracture existed, but in a few minutes after the fall he expectorated some blood-streaked sputum. Ten hours after the accident a fever of 104, pulse 138 and respiration of 52 were observed. The sputum became thoroughly mixed with blood and rusty. This case was prolonged, ending in lysis the fourteenth day after the advent of fever. Convalescence was slow, and the patient never recovered fully from a bronchial catarrhal condition, with numerous streptococci, but no tubercle bacilli in sputum. This case is still under observation. The chest is of paralytic appearance and conformation, and the subject admits the history of former bronchial catarrh, but claims that it was but temporary.

One of the most remarkable cases in the writer's experience was that of a man aged 31 years, 5 feet 8 inches in height, weight 168 pounds, of good family history

and excellent health, a puddler by occupation, who was struck forcibly upon the right anterior portion of the chest by the handle of the tongs with which he was transferring a ball of metal. He immediately became faint and was seized with dyspnea. A physician examined the chest without discovering any external or internal signs of injury, except a swiftness of respiration. After the use of hypodermics of strychnia, brandy and other antidotes to the shock, he was able to go to his home by street car, a distance of about four miles. Here he received attention during the succeeding four days, and the diagnosis was pneumonia. The temperature, pulse and respiration, rusty sputum, etc., were in evidence in the history, as related to the writer, who was called in consultation on the fifth day, because of the alarming dyspnea which suddenly appeared. The patient was on his knees on the floor pressing the anterior portion of the chest against the mattress and begging for relief for his breathlessness. His features mirrored his desperate suffering. The side opposite to the pneumonia was distended to its utmost by pneumothorax. A paroxysm of severe coughing had preceded the pneumothorax, and doubtless produced a bronchial communication with the pleural cavity belonging to the lung engaged in supplementary respiration. The discomfort was reduced by a hypodermic injection of morphia gr. ¼, repeated in two hours. The proposition to use a trocar and give exit to the air was persistently rejected. After twelve hours it was determined to give surgical relief, regardless of the patient's opposition. At the hour appointed for the operation the patient was lying calmly in bed, the signs of distress had departed, respirations were reduced from 56 to 40, the pulse from 132 to 110, and the temperature had fallen 3.8 degrees. The physical signs of pneumonia were not gone, neither were those of pneumothorax wanting, but to each side they were much reduced, and the operation was abandoned, and the case progressed to a favorable termination of the pneumonia, which had ended by crisis, but the evidence of effusion succeeded the pneumothorax. The patient, notwithstanding all this, gained flesh, refused to have the fluid removed, and worked six months at the puddling furnace, after which he visited his home in Scotland, returning to his duties at the end of four months. He presented himself for examination one year and two months following the accident with a pyopneumothorax which had evacuated itself of one pint to three pints of pus through the mouth, repeating the evacuations at intervals of twelve to sixteen days. Specimens of this fluid examined on several occasions revealed numerous tubercle bacilli, streptococci and other microorganisms. This spontaneous method of relief continued during seventeen months, when it ceased, and the pleural cavity became distended, to finally present an empyema necessitating pointing between the ninth and tenth ribs on the vertical midscapular line. A hectic condition continued the pulse, temperature and respiration elevations for some time.

He was taken to the hospital and the chest opened, drained and washed out and treated with antiseptics. After three weeks he returned to his home much improved, but gradually yielded to phthisis eight months thereafter.

The study of these cases must include their medical, surgical and legal aspects. This has been advanced by references to numerous authorities and cases. Diagnosis, differentiation and treatment are so interwoven that it seems like supererogation to go into any further detail. The prognosis has been intimated. The medical treatment should be similar to that of ordinary pneumonia plus the demands of the surgical contributions. Complications or sequelæ are also subject to general and well-known medical and surgical management.

VERNAL CONJUNCTIVITIS.*

WM. CAMPBELL POSEY, M.D.
PHILADELPHIA.

So little is understood concerning the pathogenesis of vernal conjunctivitis, and its treatment is so generally ineffective, that it occurred to the writer some months ago to address a circular letter to ophthalmic surgeons throughout the United States, with a view to ascertaining their experience in studying and treating this rare form of disease, and especially for the purpose of determining whether locality influenced the frequency of its occurrence or modified its clinical manifestations.

The paper which follows has, accordingly, been based in large measure on the answers which were received, together with a few personal observations which the writer has been enabled to make on a number of cases which have come under his own care.

HISTORICAL SUMMARY.

Before proceeding with this, however, on account of the rarity of the disease and the still comparatively scanty literature upon it in the English language, it may not be amiss to review briefly its history and chief characteristics. Although Arlt, in 1846, undoubtedly referred to this disease in a paper in which he described "Three Cases of Infiltration of the Limbus by Grayish Yellow Transparent Gelatinous Masses," and Desmarres likewise, when he referred to cases of what he designated *hypertrophie perikeratique de la conjunctive,* it was not until 1872 that vernal conjunctivitis was assigned a place as a distinct and separate form of disease, by Saemisch and his pupil, Brockhaus. In addition to Arlt and Desmarres, Graefe, de Wecker and Hirschberg had also reported cases which were beyond doubt true instances of vernal conjunctivitis, but they assumed, in common with Desmarres, that they were dealing with unusual forms of phlyctenular disease.

Saemisch's account of the disease is very complete, and the symptomology which he gave of it is much the same as we know it to-day, with the important exception, however, that he failed to include in his description any lesions of the palpebral conjunctiva. These, which are probably the most common, and certainly the most characteristic features, were first noted by Raymond in 1876, and described more fully by Vetsch in 1879. Since that time a number of important monographs have appeared which have further established the propriety of classifying it as a distinct form of conjunctivitis. Burnett, of Washington, was the first to call the attention of American ophthalmologists to it, in an article which appeared in 1881, entitled "Circumcorneal Hypertrophy of the Conjunctiva." In 1884 Kipp, of Newark, made the second contribution to the American literature. Since then Gifford, Gradle and May have made communications of value and importance.

Vernal conjunctivitis, as we know it to-day, and as it occurs in all probability the world over, consists of an inflammation of the conjunctiva, at times of the lids alone, at times of the globe alone, and not rarely of a combination of these two, possessing certain physical

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. J. A. Lippincott, Frank Allport and John E. Weeks.

features which distinguish it from all other forms of conjunctivitis, but which has, in addition, the peculiar characteristic of appearing with the advent of warm weather and of disappearing with the cold, and of repeating this peculiarity year after year. This seasonable characteristic, whence the name of the disease is derived, is the essential feature of vernal conjunctivitis.

The physical appearances of vernal conjunctivitis are as follows:

I. LESIONS OF THE PALPEBRAL CONJUNCTIVA.

(*a*) The most constant, and perhaps the pathognomonic symptom is a peculiar bluish white, milky appearance of the tarsal conjunctiva. Vetsch was the first to describe this condition, which is present in a greater or less degree in nearly all cases. In the few instances where it is not present the conjunctiva appears dull, infiltrated and thickened.

(*b*) The surface of the thickened conjunctiva may be smooth; usually, however, there are a number of elevations which present a striking appearance, resembling the granulations of no other form of conjunctival disease. These elevations present a pale pinkish, waxy appearance, and are quite flat, resembling plaques with crevices between. They are situated on the tarsus, the fornix being free, and are usually thickest in the middle of the lid. They are slightly pedunculated.

(*c*) In another and smaller group of cases the granulations are not so flattened, are yellow, semi-transparent, and cover more of the conjunctiva of the lid. These bear a close relationship to the granulations in follicular conjunctivitis.

In all three types the upper lid is the most affected, the conjunctiva of the lower lid being rarely more than thickened, with but a few elevations on it. The granulations are hard and gristly, this being especially true of the more rounded variety. A watery or mucous discharge is more or less constant, rarely it becomes mucopurulent, but never purulent.

II. LESIONS OF THE OCULAR CONJUNCTIVA.

(*a*) The limbus of the cornea becomes thickened and encroaches upon the cornea, forming a narrow ring of grayish yellow opacity, which encircles the cornea. The inner edge of this zone is sharply circumscribed; the outer blends gradually with the surrounding tissue. This area of infiltration does not show any tendency to broaden and invade the central portion of the cornea, or to break down into ulcers.

(*b*) Large yellowish red elevations, more or less circumscribed, appear at the limbus in the palpebral fissure, either on the nasal or temporal side, or on both. These are usually somewhat triangular in shape, but may be oval or quadrilateral. When the former, the base of the triangle is situated at the limbus, and is sharply defined from the corneal tissue, while the apex blends gradually with the episcleral tissues toward the equator.

(*c*) Under this class is included a combination of the first and second forms; in this type the entire limbus of the cornea is thickened and occupied by a series of irregularly rounded warty like tumors, grayish yellow in color. The inner edge of the zone of infiltration is not so sharply defined as in the two preceding types, and at times the corneal tissue is encroached on to a considerable extent. No case has been reported, however, where this was sufficiently marked to affect vision.

(*d*) Ordinary saturated ulcers of the cornea, which sometimes result from pressure and irritation, occasioned by unusually large and hard granulations in the palpebral conjunctiva. The tumors or elevations which surround the cornea are like the granulations in the conjunctiva of the lids, hard, dense, and as a rule non-vascular. They are not painful on pressure.

It is extremely rare that the disease occurs in the typical form, exhibiting the characteristic lesions of the tarsal and bulbar conjunctiva at the same time; though even in those cases where the elevations are most marked on the bulbar conjunctiva, there is usually at some time or other during the course of the disease, at least the milky haze, if not the characteristic granulations, on the tarsal conjunctiva. Terson has pointed out that often there is a kind of compensation between the tarsal and the pericorneal lesions, the characteristic changes being absent in one part when they are present in a marked degree in the other.

PATHOGENESIS.

Various observers have thought the disease to be dependent on a diathesis, and syphilis, scrofula, rickets, gout, and a general neurotic condition have been variously described as the soil upon which vernal conjunctivitis develops. It is possible, however, to exclude each of these in most cases, the disease occurring for the most part in perfectly healthy subjects; nor is there evidence, as will be more fully stated later, to assume that the disease is secondary to any local inflammation elsewhere, as in the throat or nose. In this connection, however, mention must be made of the relation of vernal conjunctivitis to recurring skin eruptions, by reason of the frequency with which eczema has been encountered in cases of vernal conjunctivitis by foreign observers, among whom may be mentioned Uhthoff, Vetsch, Danvers and Terson.

It is generally recognized that vernal conjunctivitis shows a predilection to develop in low-lying localities, the testimony of men from mountainous regions being that they see but few cases, and none at all from the highlands. The influence of humidity in aggravating the symptoms has been remarked, and the conjunction of a high temperature and high barometer has been found to be most distressing to subjects of the disease. Although certain authors would have it that a country life predisposes to the affection, there is no evidence to prove this, as it appears that city life, with the irritation provoked by the dust from the street and by the smoke with its carbon particles suspended in the air, offers as favorable conditions for its development.

Unlike most forms of conjunctivitis, vernal conjunctivitis affects all grades of society. All races are apparently equally susceptible, both whites and blacks being subject to it, and the disease seems to occur with the same relative frequency among the Jews.

On account of the recurrent nature of the affection, a micotic origin has been repeatedly searched for, but as yet no pathogenic micro-organism has been isolated.

It was thought by some, by reason of a certain similarity in their physical appearances, that vernal conjunctivitis was a form of trachoma. Until the morbid entity of both diseases is better understood, it is impossible to deny absolutely a relationship between the two, but the course and sequelæ of both diseases are so different that there are but few who now hold to such a theory. In like manner, there is no evidence to support the theory of an association with phlyctenular conjunctivitis; indeed, though Knus would regard vernal conjunctivitis as a peculiar hyperplastic conjunctivitis in intermediate relationship with the ordinary inflammations of the conjunctiva, and thinks that the disease is a modification, or at any rate develops

from these, there are no grounds to couple it with any form of other ocular disease.

PATHOLOGY.

An excellent résumé of the histological changes which have been seen by various observers in vernal conjunctivitis, has been recently given by Terson. This author states that with few exceptions writers have given an excessive preponderance at one time to the epithelial nature, and at another to the subepithelial character of the granulations; so far as he is concerned, however, he agrees with Redmond in holding that the epithelium, although proliferated, does not constitute the mass of the neoplasm, but that the granulation is really a proliferation of the conjunctival tissue itself, with the increase in the number of elongated and narrowed cells, and also of embryonal and round cells.

In common with others, Terson noted that the histological changes differ somewhat in the pericorneal and tarsal forms; thus in the former he found a thickened epithelium of stratified pavement cells of a greater number than normal, but without the invagination noted by most authors; there was no well defined basal membrane; the tissue contained vessels, dilated capillaries and lymphatics, but was lacking in cells; the conjunctival cells were flattened and fusiform, and were compressed between enormous bands of fibrous connective tissue. In addition to these changes, he observed that the tarsal granulations are provided with an epithelium which is less abundant, though of the same nature, and without epithelial invaginations, the mass of the tissue being equally fibrous, though the infiltration with round cells and with leucocytes is much less marked. In this class of cases there is a proliferating tarso-conjunctivitis, a true papilloma of the tarsus, greatly hypertrophied and proliferated with elements which are newly formed and without the enormous lymphatic nests of trachoma. It was noted that in the tarsal variety the epithelial proliferation is less important than in the pericorneal, and that the typical granulations are formed by the subepithelial tissues.

Terson concludes finally that, as a mark of differentiation from the granulation of trachoma and the pustule of phlyctenular disease, the vegetation of vernal conjunctivitis is indurated, and he regards it as being really an attenuated papilloma which does not attain the composite structure and full development of the true form.

These views are substantially those of Danvers, who based his observations on a series of specimens, some of which were taken from eyes at the very commencement of the disease, others in the third year of the recurrence, and others after the tenth year of recurrence.

From the study of sections of the tarsal conjunctiva taken from three cases and mounted for him by Dr. E. A. Shumway and Dr. Harold Goldberg, the writer found a dense fibrous tissue beneath the epithelium which had apparently occasioned the elevations. The epithelium between the contiguous elevations could be seen to dip down below them in finger-like prolongations from the surface. Sections made parallel to the surface showed a network of epithelial cells with the spaces in it filled with dense fibrous tissue, each patch of fibrous tissue having a central blood vessel.

SUBJECTIVE SENSATIONS.

The disease usually begins, like an ordinary attack of catarrhal conjunctivitis, with smarting, burning and lachrymation, though an annoying itching sensation in the lids is apt to predominate. These symptoms persist with remissions during the course of the disease, being aggravated by hot murky conditions of the weather and ameliorated on dry and cool days.

COURSE.

The symptoms usually begin with the first warm days of spring, and persist until the days become permanently cool in the autumn. The disease is essentially chronic, recurring each year with obstinate persistency. In a few cases there are remissions, the symptoms failing to manifest themselves during an entire summer, this exception being attributed by Danvers and others to a relatively low humidity during these particular years.

DIAGNOSIS.

In its typical, or even under the forms under which vernal conjunctivitis usually presents itself, there should be no difficulty in differentiating it from any other form of conjunctivitis, provided, of course, the observer is familiar with its characteristics, either by study of a previous case seen by him or from a familiarity with the description of the disease as it now appears in all text-books on ophthalmology. In atypical cases, however, the diagnosis is not always an easy matter, and it will often need the history of attacks in previous springs to enable one to differentiate the not uncommon type where the filmy white appearance of the conjunctiva, the granulations and the lesions at the limbus are wanting, and the dull, thickened, infiltrated conjunctiva is the only apparent lesion, from an attack of phlyctenular conjunctivitis. But even in these cases the milky hue of the conjunctiva and granulations will usually manifest themselves if the case be kept under observation a few weeks.

Undoubtedly, however, the greatest difficulty in diagnosis is to differentiate the rather unusual type in which the granules are not flat, but round, and of a semitransparent pinkish yellow tint, from trachoma or from follicular conjunctivitis. Here the history of the case, the absence of pannus and discharge, will enable one to exclude trachoma, while the restriction of the granules to the upper lid, and to the median portion of the tarsus, and the hard, gristly nature of the granules, will make the diagnosis from follicular conjunctivitis. When the palpebral manifestations are absent and those at the corneal limbus are alone present, it is possible that vernal conjunctivitis may be confused with epithelioma, sarcoma, episcleritis, phlyctenular keratitis, gerontoxon, and certain pericorneal hypertrophies and verrucosities which are occasioned by sclero-choroiditis anterior. The history of the case, the age of the patient, and in doubtful cases the microscopic examination of a portion of the growth, will usually enable one to make the differentiation from tumors, while the diagnosis may be made from episcleritis and phlyctenular disease by the absence of signs of inflammation.

Such is a brief outline of the history, of the generally accepted clinical picture and of the pathogenesis and histology of vernal conjunctivitis, and of its diagnosis from other forms of ocular disease. Other details, in reference to its etiology, distribution, frequency, prognosis, treatment, etc., will now be considered, especially with a view to the expression of the views of American ophthalmologists on these subjects, as they have embodied them in their answers to the circular letter already referred to.

Can You Estimate the Proportion of Cases of This Disease in Your Locality, in Comparison With Other Forms of Conjunctivitis?

This, the first question, elicited a series of answers which were puzzling, and might have been misleading had several factors not been taken into consideration before any deductions were drawn from them. It was apparent, in the first place, that answers which were practically at variance with one another came from ophthalmologists in the same vicinity, often in the same cities and towns, all being based upon observations of ocular disease occurring among members of the same community. Where one would state that he saw ten cases of vernal conjunctivitis annually in his private and hospital practice, another would say that although he had been practicing in that community for twenty years or more, and had observed thousands of cases of ocular disease, he had never encountered one which he considered to be a true instance of vernal conjunctivitis. Thinking there must be some explanation for this, the writer had further communication with a number of those who disclaimed ever having seen a case, and elicited from most of these that they had been looking for typical examples, and relegated all others to other forms of conjunctivitis.

Taking this factor into consideration and making allowances for "the personal equation," in a number of instances, it was ascertained that vernal conjunctivitis existed in all parts of the United States, always as a very rare disease, but exceedingly uncommon in New England, the Northwest and the highlands of all the states, and that it occurred in most of the large cities of the other parts of the country, inland as well as seaboard, in the proportion ranging from one case of vernal conjunctivitis to every 200 to 500 of conjunctival disease.

Certain observers give a greater relative frequency and others a far lower, but this proportion is a conservative estimate of the average.

It was noted that the percentage of cases was higher in private than in hospital practice, but this, it is thought, may be explained by the lesser frequency with which all forms of conjunctivitis occurs among the better classes, and also by the fact that sooner or later, by reason of its intractability, nearly all cases of vernal conjunctivitis are brought to the private consultation of the ophthalmic leaders in every community.

It is difficult to ascertain how these figures compare with those obtained in other lands, but from personal observation and from communications received from Fuchs of Vienna and Collins of London, and from Terson's studies in Paris, the writer would judge that it occurred in these cities with about the same frequency as in the larger American cities. There is an impression among American ophthalmologists, particularly those who have spent some time in foreign clinics, that vernal conjunctivitis occurs more frequently abroad than at home. The writer, however, would recall to such the large number of patients in attendance at most foreign clinics, and that as students they saw all the rare cases in each clinic. Danvers quotes a number of statistics regarding the frequency of the disease in foreign lands, but does not mention the proportion in which the disease occurs with other cases of conjunctivitis, merely giving the frequency of its occurrence among the total number of cases. He found that as a general rule the disease is more prevalent in southern than in northern countries.

Do You Think This Disease Is Becoming More Prevalent?

From the answers received to this question, there seems to be no ground for the belief that vernal conjunctivitis is increasing in frequency, the relatively greater number of cases which have been observed in recent years being due, in all probability, to a more widespread knowledge of the disease, especially in its atypical forms.

Which Type Predominates in Your Locality—the Palpebral, Where the Disease Is Limited to the Conjunctiva of the Lids, or the Ocular, Where There Are Distinct Changes at the Corneal-Scleral Margin, or the Associated, Where Both Palpebral and Ocular Types Are Combined?

This question had a two-fold purpose; first, to ascertain whether locality had any influence upon the physical appearance of the disease, and secondly, to determine the relative frequency of occurrence of the various types. In regard to the first, it was apparent that locality has no influence whatever upon the type which the disease assumes, for upon this phase of the subject similar answers were received from the most widely separated parts of the country; bearing upon the latter point, the answers were most instructive, for they showed that the palpebral type was much the more common (60 per cent.), that the associated form occurred next in frequency (30 per cent.), while the disease was limited to the ocular portion of the conjunctiva in but 10 per cent. of the cases. It is possible that the percentage of cases of the palpebral type is even higher, as many cases of this type are doubtless overlooked, either from the patient not seeking relief, or from the ophthalmologist not recognizing it, by a failure to evert the lid; when the changes are at the scleral-corneal margin, the diagnosis is more readily made.

It is proper at this point to refer to a type of the disease which Burnett, of Washington, has described in negroes. In his article, which appeared in Knapp's "Archives for Ophthalmology" (Vol. X, page 414), under the title of "Circumcorneal Hypertrophy of the Conjunctiva," this distinguished observer said that "In addition to these appearances (i. e., the typical) which I have observed in both the white and colored races, I have found quite a peculiar and remarkable appearance in the conjunctiva in every case of this disease I have met with in the negro. This consists in a brownish discoloration of the conjunctival tissue, most intense at the scleral base of the mass, and gradually fading away toward the equator of the ball. This discoloration, which is undoubtedly situated in the conjunctival tissue itself, as well as in the epithelial layer, is not regular in its distribution, but appears to consist of a collection of small deposits of brown pigment. These deposits are sometimes collected in rather large masses, particularly near the base of the elevation, but toward the equator they appear as small brownish specks in the dull and succulent conjunctiva. In some instances this brownish discoloration extends but 3 mm. from the circum-corneal elevation, while in others it reaches almost to either canthus."

Though Philadelphia is a northern city, it has a very large colored population (60,000), and the writer is in charge of three large clinical services, two of which are situated in the quarter in which most of the negroes dwell. He has observed the changes so accurately described by Burnett, a number of times, but has always considered them to be occasioned by a marginal phlyc-

tenular keratitis, or to changes somewhat similar to those producing pingueculum or pseudo arcus senilis. The inflammation in this class of cases persists all the year, is not associated with the peculiar whitish film and flattened granulations of the palpebral conjunctiva, and usually yields readily to tonics and the local remedies prescribed in phlyctenular keratitis. To obtain further testimony regarding this subject, special letters which covered this phase were addressed to a number of eminent southern ophthalmologists, and the replies of all indicated that while they had observed vernal conjunctivitis in negroes, they had found that it assumed its ordinary form in this race also, and that though they were familiar with the changes observed by Burnett in the limbal tissues of these subjects, they did not consider them to be in all instances due to vernal conjunctivitis, but in most cases to be the result of a localized inflammation of the limbus, as they considered that there was a tendency to a thickening of the tissues at the margin of the cornea in most inflammatory diseases of the eye of the negro.

Do You Often See the Peculiar Flattened Fungoid Elevations of the Palpebral Conjunctiva Referred to in the Text-books; or does the Disease Take the Form of a Thickening of the Conjunctiva Without the Development of the Elevations?

In the description of the clinical varieties under which vernal conjunctivitis might occur, the writer divided the palpebral forms of the disease into three classes; (*a*) those which present the milky white appearance of the conjunctiva, and others where this is absent, but in which the conjunctiva is dull, infiltrated and thickened; (*b*) those in which the conjunctiva is covered by rows of flattened elevations, and, (*c*) those in which the granulations are round and yellow, and harder than in the preceding variety.

From an experience gained by carefully following three cases during the past ten years, and a dozen or more for shorter periods, the writer is of the opinion that the first two forms represent but different stages in the development of the disease. In the first year or two, before the disease has persisted sufficiently long to produce very marked changes, the conjunctiva is in the condition described under class (*a*). After several years of recurrences, however, and proliferation of the epithelial tissue, elevations form, which attain a greater growth each year unless treatment is inaugurated. Such elevations are usually flattened, but occasionally assume a rounded form. This latter type is most intractable to treatment, persisting through the winter, and manifesting a tendency by the size and hardness of the granulations to injure the cornea by mechanical means. Cases of this type resemble trachoma, and it is probable that May referred to these in his report of six cases of mixed forms of trachoma and spring catarrh. From a careful reading of his article, it does not appear to the writer that May substantiated a diagnosis of trachoma in any of these six cases, the slight cicatrization in the conjunctiva being readily explainable by the employment of caustics and operations of expression, and the faint trace of pannus to an irritation of the cornea by the granulations.

From the answers received to these questions, it was apparent that elevations in the conjunctiva appeared in about 60 per cent. of all cases, though in many they were but slightly marked.

Have You Found Both Lids to Be Affected, or Have You Noticed a Predilection of the Disease to Attack the Upper Lid?

The majority of the answers showed that both lids were, as a rule, affected, though the lower lid rarely manifested more than the thickening already referred to, the milk-white haze and the elevations being seen only on the upper lid. Callan, of New York, explains the occurrence of the granulations on the upper lid, to the greater pressure to which the conjunctiva of that lid is subjected, and believes that this excites tissue changes, analogous to the growth of a corn on the foot.

Have You Ever Seen the Disease Limited to One Eye?

Vernal conjunctivitis is essentially bilateral, though from the answers received it is apparent that in a small number of cases (7 per cent.) it may be limited to one eye. It is possible, however, that even in these few cases, the observers may have seen the disease in an early stage, and that manifestations appeared later in the fellow eye.

Do You Think the Peculiar Whitish Coloration of the Conjunctiva the Most Constant Symptom of the Disease?

From the statistics it was learned that the conjunctiva presented a milky white appearance in 70 per cent. of all cases. This sign was present in every instance in the palpebral variety except in those which were characterized by the rounded variety of granulations and in another small number where the conjunctiva was dull and thickened. This appearance must be regarded as the pathognomonic physical sign of the disease, as the pathologic changes on which it depends, i. e., the thickened epithelium augmented later by the formation of a delicate subepithelial film of cicatricial tissue, must occasion it sooner or later. It is usually an early manifestation.

What Have You Found to Be the Age Limits of the Disease?

The experience of American ophthalmologists corresponds with those of European observers in regard to the age limits, cases being cited in the statistics occurring at ages ranging from 18 months to 50 years. The majority concurred, however, that the disease had its most frequent manifestation between the years of 6 and 16, and that it was very rare in individuals over 40 years of age. Desmarres noted that the disease could occur in very young children, at times almost congenitally. The writer has observed a well-marked case of the pericorneal type in an infant of 8 months, and Fuchs writes him that he has treated the disease in a man over 60 years of age. Risley reports a case in a man 50 years old.

Have You Observed Vernal Conjunctivitis in Females, or Do You Think Males More Liable?

The statistics obtained from the answers to this question showed that the experience of American ophthalmologists was analogous to that of Knüs, 85 per cent. of whose cases were males and but 15 per cent. females. A number recorded never having seen a female affected by the disease. No explanation of this comparative immunity of women has yet been offered.

At What Month Does the Disease Usually Appear in Your Neighborhood, and When Does It Disappear?

As would be supposed from the earlier advent of hot weather in the south, answers from the southern ophthalmologists showed that the disease appears earlier there than in the north. This subject is best considered under two headings; first, as regards subjective symptoms, and, secondly, objective signs. The former appear during the first few warm days of spring, and disappear entirely only with the cold weather of the autumn; the objective signs may, however, persist through the entire year—and this is particularly true of cases exhibiting

the hard rounded granulations in the conjunctiva and those with large prominence at the limbus, though occasionally a few flat granulations, and more rarely the whitish film of the conjunctiva will persist through the winter months, even in comparatively mild cases.

Although the time at which the disease first appears varies each year, according to the temperature, the first symptoms manifest themselves, as a rule, in the northern states in March or April, and in the southern states a few weeks earlier. By October all acute symptoms have usually disappeared. It has been the experience of the writer that when the atmospheric conditions which favor an outbreak of vernal conjunctivitis are present, that many of those who had been under his care in previous years for this disease, would consult him within a few days of one another, giving unmistakable evidence of the relationship existing between the various types, and enabling him to classify several cases as vernal conjunctivitis of whose precise nature he had been up to that time somewhat in doubt. He would also call attention to the fact already noted by others, of the influence which humidity has in precipitating attacks, the two factors of excessive humidity and high temperature being apparently necessary for an outbreak of the disease.

Have You Found That the Disease Grew Less Marked in Succeeding Years?

It was learned from the consideration of the ninth question that it was only in very rare cases that vernal conjunctivitis was seen in subjects after 40 years of age; it was judged from this that either when this age was attained, the pathogenic agent producing the disease had exhausted itself, or that by that time changes had occurred in the tissue of the conjunctiva which rendered it immune to the particular agent causing the disease. It was hoped that the answers to this question might determine whether there was not some limitation other than age, and whether the hope could not be extended to subjects of the disease that although treatment appeared ineffectual in curing the attack in any one year, nevertheless changes were wrought by it which would occasion a disappearance of the symptoms after a period of years. The writer's observation of nine cases which he has been able to follow by comparatively frequent study, for the past six years, indicated that though the disease persists in most instances for six or eight years, it loses its activity after that time. The observation of others corroborates this, as well as the rarity of the disease, for did it persist in all instances from the time of its first appearance, in early infancy perhaps, with annual manifestations, until adult life was attained, it would be much more commonly met with than is the rule; although Weeks speaks of a case in which recurrences had taken place every year for seventeen years, and Schwenck has followed a case since 1885, who has had yearly remissions.

It may be stated in general that the disease shows a tendency to become less marked from year to year; there may be years when, owing to some unusual climacteric influences, or to some special systematic condition of the patient, the symptoms are aggravated, but generally speaking, they seem to lessen as years go by. Whether this may be attributed to the persistence and continuance of treatment, or to changes in the ocular tissues themselves, can not be ascertained.

The prognosis, therefore, of vernal conjunctivitis may be stated in general terms to be good, for although the duration of the disease is protracted, and its symptoms so annoying in many cases that all use of the eyes must be suspended during a considerable period of each year, the ultimate issue is favorable, for with the exception of the ulceration of the cornea, which is occasioned in a few instances by the hard and horny granulations in the comparatively rare form of palpebral involvement, the center of that membrane is unaffected. As a general rule, the disease disappears wholly, leaving no trace in either the lids or the eyeball, though in a few cases certain changes occur which detract from the appearance of the eye from a cosmetic standpoint.

The most constant of these is a white ring of opacity on the margin of the cornea and a slight drooping of the upper lids, which imparts a sleepy look to subjects of the disease.

Have You Found Any Connection Between the Ocular Disease and Any Other Local Disease, Such as the Nose and Throat?

Upon account of the close anatomical connection between the mucous membrane of the eye and nose and pharynx, most cases of vernal conjunctivitis present symptoms of more or less irritation of the nose and pharynx. This has occasioned in the minds of many the belief that the inflammation of the mucous membrane of the eyes was secondary and dependent on a disease of the naso-pharynx. The answers would indicate that a number of American ophthalmologists held this view, which agrees with the observations made abroad by Coüetoux, Tétan, Silex, Danvers and others; the writer, however, quotes the opinion of the majority of American observers when he states that he believes the naso-pharyngitis to be purely of secondary origin, and to be explainable in the words of Bennett, of Buffalo, as follows: "The lacrimation in these cases is often excessive, and the carrying off of so much extra fluid into the nose causes the turbinals to become soggy, and the nostrils to become wholly or partially occluded. The proof of this to my mind is that when the elevations in the lid are removed, the excessive lacrimation ceases and the catarrh rapidly subsides."

In 1886 Gradle, of Chicago, reported four cases of a disease of the conjunctiva, which, by reason of their periodicity—lasting only during the warm season—suggested to him that they represented the pathologic entity known as hay fever, localized, however, entirely or principally in the conjunctiva. Although there was no manifestation on the globe, the changes in the tarsus were characteristic of vernal conjunctivitis. In a later paper (1895) this author states that the etiology of the affection is unknown, and adds that none of the cases observed by him presented the history of annually recurring typical hay fever.

Have You Ever Known the Disease to Be Contagious?

All of the answers to this question were negative, with the exception of that received from Weeks, of New York, who replied that "often two or more in a family were attacked, a fact which points to a contagious quality," although he adds, "it is possible that infection alone may explain the manner of the acquisition of the affection in all of the cases that come before us."

Have You Ever Known the Disease to Be Hereditary?

Although the answers received to this question would tend to corroborate the view held hitherto, that the disease is not hereditary, a number of replies were received which indicated that the reverse might sometimes be true. Thus Wilder, of Chicago, cites the case of a boy 6 years old, whose mother gave a history of having had attacks of vernal conjunctivitis for a number of years, although an examination of her eyes made at the same time with her son's, showed no signs of it. Stevenson,

of Ohio, saw both mother and daughter affected. Jackson, of Denver, thinks that he has seen instances where the disease was transmitted to the second generation. Theobald, of Baltimore, reports cases of the palpebral variety occurring in both father and son; and finally, Gifford, Tiffany and several others believe the disease to be sometimes hereditary.

What Treatment Have You Found Most Efficacious?

The chief interset of the clinician in vernal conjunctivitis undoubtedly centers in the treatment, for there is perhaps no other disease in the realm of ophthalmology which has been found to be equallly resistant to all therapeutic effort. There is scarcely a drug or a measure which could exert any possible beneficial action on the conjunctiva which has not been essayed. On account of the resemblance of the granulations to those of trachoma, treatment which was known to be of service in controlling that form of conjunctival disease has been generally tried, but in most cases the caustics employed were found to aggravate the symptoms, and removal of the granulations by grattage or excision was usually followed by their rapid reappearance. Milder astringents have also been employed, but from the answers which have been obtained, the experience of American ophthalmologists is apparently in agreement with that of foreign authors, that while remedies may be at times of service in relieving acute symptoms, none have been found which exerted a curative influence. Among the drugs which have proven most valuable in alleviating the symptoms and shortening its course, are mentioned weak solutions of silver nitrate, or its substitutes, protargol and argyrol; formaldehyd solution and protargol 4 per cent., hydrastin, holocain, antinosin, solutions of adrenalin chlorid, dilute acetic acid, the chlorid and sulphocarbonate of zinc, ointments of yellow oxid of mercury, of salicylic acid and of lanolin. While the writer is forced to acknowledge the intractability of this disease in many cases, he still believes that there is reason to approach the conduct of cases of vernal conjunctivitis with some confidence of success. In the first place, he would insist upon the value of certain prophylactic remedies which should be applied to the conjunctiva for some weeks or even months before the annual attack in the spring is expected. For this purpose he employs weak astringent washes with occasional massage of the conjunctiva with unguent hydrarg oxid. flav. (½ per cent.). Casey Wood massages the conjunctiva with lanolin to obtain the same result. Any constitutional disturbance is corrected and general hygienic measures enjoined, such as out of door exercise and cold bathing. If well borne, arsenic should be administered internally, as a number of foreign observers think they have established the connection between this disease and certain eczematous skin eruptions. If despite these precautionary measures, the symptoms of the disease appear, then if this be the first attack the patient should be advised of the nature of the affection, and should be counseled to restrict the use of his eyes at near work on the days when his symptoms are most intense, and to remain as much as possible in a cool, darkened room, out of the irritation of the sun's rays. Dark glasses should be worn in the light. Iced compresses should be maintained almost constantly, and all lotions which are to be instilled should be iced also. The lids should be anointed from time to time with a salve of the yellow oxid of mercury (½ per cent.). A mild antiseptic nasal spray may be employed, but as the writer has not been able to satisfy himself of any causal relationship existing between the irritation of the nasal pharynx, which is present in most cases, and the conjunctivitis, he does not think any special treatment of the nose or throat necessary. The drugs which are to be employed locally will depend largely on the type of inflammation which the disease assumes; if, as is usually the case, the tarsal conjunctiva is alone affected, and the granulations have not attained great size or density, mild antiseptic washes, either of boracic acid or boracic acid and cocain (acid boracic gr. x; cocain, gr. ii to f. ℥i) or of bichlorid of mercury (1-5,000) or of dilute acetic acid (gtt. x ad. f. ℥i), should be used at frequent intervals to keep the eyes clean and freed from secretion. In addition to this, a solution of adrenalin (1-5,000) will be found not only to bring great relief to the symptoms, especially to the itching which is always so troublesome, but to exert a marked influence upon shortening the course of the disease. Weeks has found the insufflation of calomel powder on the palpebral conjunctiva in an extremely thin layer, once in every forty-eight hours, to be of service.

In cases of longer standing, where the granulations are larger, but still flat and not yet of gristly consistency, the same lotions may be continued, but more powerful alteratives should be employed, such as either a solution of corrosive sublimate (in the strength of 1-5,000); massage of the lids with an ointment of yellow oxid of mercury (2 to 4 per cent.), or the application of boroglycerid and protargol 4 per cent. Suprarenal solution with chloretone, and a solution of formaldehyd and protargol are often of value. The persistent use of weak (¼ per cent.) solutions of nitrate of silver is of service in this variety also, especially if there be much associated catarrh of the conjunctiva. If the granulations still persist, despite these remedies, recourse should be had to electrolysis or the actual cautery, but excision of the granules by the knife should not, in the opinion of the writer, be performed in this stage, for it is possible, indeed usual, for such granulations, even those of large size, to disappear wholly on the advent of cool weather, and for the conjunctiva to assume a perfectly normal appearance. It does not seem justifiable, therefore, to employ a method of treatment which might produce permanent changes in the lids and lead to troublesome complications. Cauterization of the granulations by strong acids, such as chromic, is also to be depreciated.

In the third variety of the tarsal type, that in which the granulations have become hard and gristly and are rounded, it is better to proceed at once to the removal of such granulations by surgical measures. In this type the granulations persist through the winter, though the subjective symptoms may disappear, and as they occasion a permanent thickening of the tarsus, the scar tissue which is left by their removal is less annoying and disfiguring than the presence of the granulations themselves. The removal of the granulations in this stage is not an easy matter. The roller forceps will be found useless, and it is impossible to express the contents of such a granulation, even after it has been incised; each granulation is really a dense fibrous body, and is best removed by shaving it off even with the conjunctiva by means of a very sharp knife. Massage of the conjunctiva with lanolin or with a salve of the yellow oxid of mercury (4 per cent.) should be steadily maintained after the operation, as it will be found that the granulations will exhibit a tendency to recur; indeed, despite these local applications, repeated removals with the knife will often be necessitated. The prompt surgical intervention in this class of cases is usually followed by the greatest

amelioration in the symptoms; and the ulceration of the cornea, which is not infrequent in this type, from the mechanical pressure exerted upon the cornea by the size and hardness of the granulations, may usually be prevented.

In the ocular type of inflammation, massage of the globe with the yellow oxid of mercury will cause the disappearance of the swellings in many instances, if these be but small; where the granulations are large, frequent insufflations with calomel are of service, but at times the cautery will have to be resorted to. In the associated form, a continuation of the double line of treatment just outlined may be employed, and it will be found that if the granulations on the tarsal conjunctiva be similarly attacked, the changes around the limbus will be seen to disappear *pari passu* with those on the lids.

It is of interest to note that Starr and Bennett, of Buffalo, have obtained benefit from exposure of the conjunctiva to the action of the *x*-rays.

Although few, perhaps, may be able to take advantage of the benefits which accrue from it, change of climate is of great importance; while, as already stated in an earlier paragraph, it is impossible to ascertain from the answers received to the circular letter whether there was any part of the country which exhibited an absolute immunity against the disease, there is general testimony that cases of vernal conjunctivitis get well quicker in a high, dry, cool climate than under any other conditions. Thus patients do better in the mountains than at the seashore. Though it should be mentioned in this connection that Kipp has found that an ocean voyage removes annoying symptoms.

Note.—The complete bibliography of vernal conjunctivitis may be found in the article by Terson appearing in *La Gaz. des Hopitaux*, July, 1898, and in the monograph by Danvers, entitled "Spring Catarrh of the Eyes," and published by J. Bale, London, 1901.

DISCUSSION.

Dr. John E. Weeks, New York—I have seen a comparatively large number of cases of this kind, the percentage being greater in the last few years in proportion to the number of cases of eye disease. It is a curious fact in my experience that these cases have occurred among the well-to-do in a proportionately larger percentage than in those whose hygienic surroundings have been less favorable. Children who live in the city during the winter and go to some country home in the summer are those who have furnished the largest number of cases. In my experience children under the age of 3 years seldom present this condition, and I do not think that I have ever seen the onset of the disease after the age of 25 years. I have, however, observed the results of this condition and a continuation of it in adults up to the age of 45 or 50 years.

The striking feature in this disease is the variability in the length of time during which it persists. I have observed it in children from whom it has entirely disappeared after the third summer. I have observed it in other cases in which its recurrence has been noted for at least eighteen years.

There does not seem to be any particular predisposition on the part of the individual to contract the disease; it occurs in the robust equally as often as in those who show evidence of relatively poor nutrition. In regard to locality, I have observed it in those who live near the seashore as well as those who live inland.
